ABSTRACT

Superantigens (SAGs) are microbial toxins that cross-link T cell receptors with major histocompatibility complex (MHC) class II (MHC II) molecules leading to the activation of large numbers of T cells. Herein, the development and preclinical testing of a novel tumour-targeted SAG (TTS) therapeutic built using the streptococcal pyrogenic exotoxin C (SpeC) SAG and targeting cancer cells expressing the 5T4 tumour-associated antigen (TAA) was described. To inhibit potentially harmful widespread immune cell activation, a SpeC mutation within the high-affinity MHC II binding interface was generated (SpeC_{D203A}) that demonstrated a pronounced reduction in mitogenic activity, yet this mutant could still induce immune cell-mediated cancer cell death *in vitro*. To target 5T4⁺ cancer cells, a humanized single-chain variable fragment (scFv) antibody to recognize 5T4 (scFv5T4) was engineered. Specific targeting of scFv5T4 was verified. SpeC_{D203A} fused to scFv5T4 maintained the ability to activate and induce immune cell-mediated cytotoxicity of colon cancer cells. Using a xenograft model of established human colon cancer, it was demonstrated that the SpeC-based TTS was able to control the growth and spread of large tumours *in vivo*. This required both TAA targeting by scFv5T4 and functional SAG activity. These studies lay the foundation for the development of streptococcal SAGs as 'next-generation' TTSs for cancer immunotherapy.

KEYWORDS

colorectal cancer, superantigen, single-chain variable fragment antibody, tumour-associated antigen, cancer immunotherapy, xenogeneic mouse model

ACKNOWLEDGMENTS

Firstly, I would like to express my sincere gratitude and appreciation to my advisor Dr. John McCormick for the continued support throughout my studies, and for his constant guidance, insight, motivation, and compassion. I would like to thank him for encouraging my research throughout this journey and allowing me to truly grow as a scientist, both individually and as a collaborator. The positive research environment and opportunities has truly been inspirational and I attribute his tremendous mentorship for the reason of my continued passion for research. I truly appreciate all that has come with my time within his lab; countless skills that will undoubtedly carry through to my future endeavors.

I would like to acknowledge the sources of funding for the research provided during my tenure, including Dr. McCormick's support from Canadian Institutes of Health Research (CIHR), as well as the direct support I have received from Western Graduate Research Scholarship (WGRS), Schulich Graduate Scholarship, and Schulich Scholarship for Medical Research from Western University.

In addition to my advisor, I would like to thank my thesis advisory committee members Drs. Mansour Haeryfar and Fred Dick, for their encouragements, insightful comments, and discussions, which continually provided opportunities to widen my research from various perspectives. I would like to acknowledge Dr. Haeryfar further for the seemingly endless use of his lab equipment, reagents, and scientific techniques, providing tools and opportunities in my research that would otherwise not have been achievable.

I would like to take this opportunity to give a sincere acknowledgement to the faculty and supportive staff members within the Department of Microbiology and Immunology for their continued support for not only myself, but for all students, and for providing a network of truly talented researchers that are welcoming, helpful, and whom generate an environment of endless opportunities and facilities to foster great science.

I thank Dr. David Hess and his team, for use of his reagents, lab space, and assistance in conducting related research. I am also grateful to Delfina Siroen for all of her support,

especially for assistance with *in vivo* work and in the world of histological techniques. I would like to acknowledge the previous hard work and contributions made by Jennifer Dixon and Peter Bastedo in order to move this research forward.

I sincerely thank my fellow lab members not only for all of the stimulating discussions, scientific or otherwise, and the continuous assistance and support, but importantly, for the many, many laughs over the years, the friendships, and of course, fond memories.

Lastly, I would like to express my gratitude to all of my friends and family, in particular my parents, brother, and sister, who have wholeheartedly given support not only through this journey, but throughout every endeavor and undoubtedly any future ones. And of course, a huge thank you to Brent, my fellow labmate, best friend, and significant other, to whom, throughout our entire experience, I am greatly indebted. I truly cannot express in words how much his unconditional support has been, and will remain, appreciated.

V _L	light chain, variable domain
VEGF	vascular endothelial growth factor

vWF	von Willebrand factor
WHO	World Health Organization
WT	wild type
XELOX	capecitabine plus oxaliplatin

CHAPTER 1: INTRODUCTION

1.1 General overview of cancer

Cancer is a leading cause of both disease and death worldwide, with a recent incidence rate of approximately 14.1 million new cases and 8.2 million deaths annually (1). A generic term for a large group of diseases, cancer is “the rapid creation of abnormal cells that grow beyond their usual boundaries,” as described by the World Health Organization (WHO) (2). Initially affecting any part of the body, cancers can further spread and invade tissues and organs, with these metastases generating the bulk of death from cancer (2). According to the WHO, the multistage transition of normal cells to malignant tumours results from a combination of fundamental factors including an individual’s genetics, ageing processes, and external agents comprising of physical (*e.g.* ultraviolet, radiation), chemical (*e.g.* tobacco), or biological (*e.g.* infection) carcinogens (2). As such, the most common causes of cancer death worldwide, in descending order, are those of lung, breast, colorectal, prostate, stomach, and liver cancer (1), coordinating with the associated key risk factors of tobacco use, alcohol use, unhealthy diet, and physical inactivity (2). Additionally, in many developing countries, chronic infections are major risk factors. By modifying or avoiding these major factors, it has been estimated that more than 30% of cancer deaths could be prevented (2). Although strides in preventative screening and early diagnosis are aiding in the overall outcome of this disease, it is still expected that the number of new cases will rise approximately 70% over the next 20 years, nearing 22 million new cases annually (2).

Specifically within Canada, cancer is responsible for nearly 30% of all deaths (3). According to statistics from the Canadian Cancer Society for 2015, approximately 196 900 new cases of cancer will develop and 78 000 patients will die of this disease; numbers that are ever increasing with each year (3). As a result, almost half of all Canadians will be expected to develop this disease within their lifetime, and consequently one quarter are predicted to die of cancer. Related to worldwide estimations, it is expected that new cases will dramatically rise (79%) in Canada over the next 15 years, largely due to the ever-increasing aging population (3). Indeed, despite that this devastating disease can occur at any age, the vast majority (89%) of individuals who currently develop cancer are over the age of 50 (3). The importance of continued research

and development of additional health resources for managing this disease is highlighted from this staggering predicted increase in incidence rate. Cancers of the lung, breast, colorectal, and prostate, similar to other developed, westernized countries, are responsible for more than half of new cancer cases (51%) annually and although all cancers are of importance, may warrant particular focus due to their sheer prevalence. Current efforts, despite ongoing challenges, have made significant progress in the fight against cancer. Today, with the continuous knowledge growing in cancer biology, the risk factors, surveillance, and treatments, many improvements have been made; most notably resulting in the steady decline of the cancer mortality rate since its peak in 1988 within Canada (3).

1.2 Colorectal cancer

Colorectal cancer (CRC) represents a major health concern worldwide, being accountable for more than 600 000 deaths per year (4). Despite advances in screening and treatment, CRC remains the third most common cancer in men, 10% of the total, and the second in women, 9.4% of the total, worldwide (1). Similar to the rest of the Western world, CRC is one of the four major contributors to new cancer diagnoses in Canada, accounting for more than half of all cancers and is the second and third most common cause of cancer-related death for males and females, respectively (3). The overall 5-year survival rate is 65% (5), but varies extensively depending on the stage of CRC progression at diagnosis (**Table 1**).

Although the risk factors of developing CRC can have a hereditary component, it is more common that environmental factors are influential in its high incidence rate. These risk factors are outlined in **Table 2**. As an example, epidemiological studies have demonstrated that individuals who have immigrated to the Western world from a once CRC low-incidence country, eventually developed CRC at a similar rate to those native-born (6, 7). Moreover, evidence during the past decade suggests that the Western influence globally, in particular with diet, has caused incidence rates of CRC in these once low-rate countries to rise dramatically (6-8). Such preventable influences include elevated consumption of dairy, meat, eggs, and oil or fat, which remain preeminent in

Table 1. TNM classification of CRC malignant tumours

Stages are based on the UICC and AJCC groups with associated 5-year survival rate percentage. Modified from Meyerhardt *et al.* 2005, Sobin LH *et al.* 2011, and O'Connell *et al.* 2004 (9-11).

Stage	TNM classification	Dukes' classification	5-year survival (%)
0	Tis, N0, M0		
I	T1, N0, M0 T2, N0, M0	A B1	>90
IIA	T3, N0, M0		
IIB	T4a, N0, M0	B2	70-85
IIC	T4b, N0, M0		
IIIA	T1-2, N1, M0 or T1, N2a, M0	C1	
IIIB	T3-4a, N1, M0 or T2-3, N2a, M0 or T1-2, N2b, M0	C2	40-55
IIIC	T4a, N2a, M0 or T3-4a, N2b, M0 or T4b, N1-2, M0	C2	
IVA	T(any), N(any), M1a		
IVB	T(any), N(any), M1b	D	<10
TX	Cannot be assessed		
Tis	Carcinoma <i>in situ</i>		
T1	Invades submucosa		
T2	Invades muscularis propria (muscle layer)		
T3	Penetrates muscularis propria and invades subserosa		
T4	Direct invasion of other organs or structures, or perforates membrane lining		
	4a - perforates visceral peritoneum		
	4b - directly invades other organs or structures		
NX	Regional lymph nodes cannot be assessed		
N0	No metastases		
N1	Metastases in 1-3 nodes		
	1a – metastasis in 1 regional lymph node		
	1b – metastasis in 2-3 regional lymph nodes		
	1c – satellites in the lymph drainage areas of the subserosa or the surrounding tissue without regional lymph node metastasis		
N2	Metastases in 4 or more nodes		
	2a – metastasis in 4-6 regional lymph nodes		
	2b – metastasis in 7 or more regional lymph nodes		
MX	Presence or absence cannot be determined		
M0	None detected		
M1	Detected		
	1a – metastasis confined to 1 organ or non-regional lymph node(s)		
	1b – metastasis in more than 1 organ or the peritoneum		

Table 2. Risk factors for the development of CRC

	Risk factor associated with increased incidence^a
Unpreventable/hereditary	Age 50 ⁺ years Previous CRC or polyps Family history of CRC Inflammatory bowel disease: ulcerative colitis, Crohn's disease
Preventable	High-fat diet Diet low in fruits and vegetables Physical inactivity Obesity Tobacco use Alcohol use

^a Modified from Benson, 2007 (6)

high-fat diets of many countries today, lacking in a regular intake of fruit and vegetables (6). Furthermore, increased risk is also associated with lifestyle; inactivity, obesity, tobacco, and alcohol use of the most common factors (6, 12, 13). Indeed, location and socioeconomic status continue to be the main correlations with the incidence rate of CRC globally.

This carcinoma, unlike many other malignancies, may be potentially curable if early stage tumours are able to be removed. As such, it has been predicted that the implementation of screening programs aimed at early detection are imperative to reducing overall incidence and associated mortality of CRC (14). However, CRC is difficult to diagnose with few symptoms until the onset of stage III or IV, based on the Tumour-Node-Metastasis (TNM) classification (**Table 1**). At the time of diagnosis, approximately 20% of patients will present with inoperable CRC, and 20-25% with pre-existing metastatic disease (5, 15). Although tumour resection is performed when possible (10, 15), high mortality rates remain associated with CRC. Of those patients receiving surgical intervention, 40-50% will relapse or die from metastatic disease, the majority due to complications of liver metastases (6, 10, 15).

1.2.1 CRC development and carcinogenesis

The first CRC carcinogenesis model was described by Fearon and Vogelstein in 1990 (16) and since, the multi-stage progression of CRC and contributing influences has had significant progress in understanding its molecular pathogenesis, as well as remaining challenges, which have been the focus of many comprehensive studies and reviews (16-21). Foremost, CRCs develop gradually as a multifaceted result of epithelial cells transforming into adenocarcinomas through a sequential accumulation of genetic and epigenetic changes across multiple molecular pathways. As such, CRCs are known to be genetically diverse; each tumour has a unique combination of genetic alterations, and only a few mutations are common to CRCs (22). The pathological progression begins as a benign adenomatous polyp from a microscopic mucosal lesion, that further spreads and localizes within the submucosa and muscularis propria (muscle layer) (23). Further progression advances into high-dysplasia adenoma, potentially disseminating into

regional lymph nodes and surrounding tissues. Without intervention, non-regional lymph nodes and/or other organs may be invaded, advancing into late stage CRC of invasive metastatic disease (23).

The majority of CRC occurrences are sporadic, nonhereditary, and have complex, heterogeneous etiological factors for carcinogenesis (24). To date, at least three molecular pathways for sporadic CRC have been described. The most common subgroup, termed chromosomal instability pathway, is characteristic for accumulations of point mutations in specific oncogenes and tumour suppressor genes (*e.g. APC, BRAF, KRAS, TP53*) causing numerical and structural chromosomal irregularities (25). This pathway is mainly associated with 1) a mutation and/or loss of *APC*, functionally interrupting the suppression of the Wnt-signaling pathway, 2) mutation of the *KRAS* oncogene, consequently constitutively activating downstream signaling (RAS-RAF-MEK-ERK pathway) and 3) either mutation or chromosomal loss that contains *TP53*, encoding p53, an important tumour suppressor gene (26). Second, the microsatellite instability (MSI) pathway leads to genetic hypermutability as an outcome of misregulation of DNA mismatch repair genes (MMR) (27). In this pathway, single point or frameshift mutations occur in areas of the genome containing microsatellites, short repeat nucleotide sequences that can be inserted or deleted, from a defective mechanism (27). Although a hallmark trait of Lynch syndrome, also often called hereditary nonpolyposis colorectal cancer (HNPCC), this genetic irregularity occurs in ~13% of sporadic CRC (27, 28). Lastly, known as the CpG island methylator phenotype (CIMP) pathway, the expression of key tumour suppression genes (*e.g. MLH1*, a MMR gene) is epigenetically silenced and inactivated with hypermethylation of genetic promoter regions (29). Although there is not one universally recognized panel of CIMP markers, CRC carcinogenesis has associations with two separate genetic mutations, *KRAS* and *BRAF* (downstream of *KRAS* signaling) (30). Notably, these pathways are not mutually exclusive in the development of sporadic CRC, with this disease frequently presenting features from all three pathways (24).

A lesser proportion of CRC cases are of known hereditary decent (~20-30%) (31); ~5% of cases are associated with highly penetrant inherited mutations with well-characterized clinical presentations (32). Currently, the etiologies of the remaining 15%–25% of

inherited CRCs are not completely understood or clarified. Conditions characterized are HNPCC, commonly known as Lynch syndrome described briefly above, familial adenomatous polyposis (FAP), attenuated FAP, and *MUTYH*-associated polyposis (MAP). Lynch syndrome is caused by genomic instability from an autosomal dominant inherited germline mutation in MMR genes, eventually leading to MSI (28, 31). Although the term nonpolyposis is used for this disease, the CRC frequently develops from polyps that, once formed, tend to become rapidly malignant, affecting sufferers at an early age (mean 45 years) (28, 31). Similarly, in patients with FAP, untreated CRC develops at an early age (mean 39 years), arising from autosomal dominant germline mutations in the *APC* gene, leading to constitutively activate Wnt signaling (31, 32). Consequentially, a characteristic feature of FAP includes the cellular over-growth and development of hundreds to thousands of colonic adenomas, beginning in early adolescence, and inevitable CRC progression in untreated individuals (32). Also presenting with autosomal dominant mutations in *APC*, attenuated FAP is a less-severe form of the disease, characterized on average of thirty colonic adenomatous polyps and a later age of polyp and CRC development (32). Lastly, MAP, an autosomal recessive form of FAP and mimics presence of adenomatous polyps increasing the risk of CRC at an early age, but is caused by bi-allelic mutations in *MUTYH* (also referred to as *MYH*). Characterized as part of the base-excision repair pathway, a mechanism for DNA corrections from spontaneous and environmentally induced genotoxic or miscoding base lesions, the *MUTYH* product, a DNA glycosylase, is specifically involved in defending against oxidative DNA damage (32, 33).

1.2.2 Standard treatments for CRC

Current treatment strategies for CRC include surgical intervention when possible (34-36), chemotherapy (37-39), anti-angiogenic therapies (40-43), and epidermal growth factor receptor (EGFR) inhibitors (44, 45). To date, surgical procedures remain the basis of curative treatment for CRC, however, disease management is typically a multimodal approach of conventional chemotherapy and local radiation therapies; the combination of surgery followed with chemotherapy being most widely accepted (46). Some patients with metastases confined to liver and/or lung can be cured of initially unresectable

disease using such approaches with intensive chemotherapy and secondary resection (15), however targeted therapies have largely impacted the treatment of metastatic disease (mCRC). In particular, anti-angiogenic drugs have had an advantageous role in treatment of mCRC where they are becoming components of standard-of-care therapy, as with their incorporation into combination chemotherapy regimens, there is improvement in patient survival outcomes (41, 47-50). mCRCs unfortunately have a tendency to develop resistance to the currently available anti-angiogenic therapies, and further, conventional approaches are highly limited due to toxicity and lack of tumour specificity, ultimately maintaining a poor prognosis of metastatic disease (51) and CRC in general. The predictive and prognostic biomarkers for biological therapies of mCRC are summarized in **Table 3**.

Specifically, the standard first-line drug treatments are fluoropyrimidine-based regimes classically comprised of 5-fluorouracil (5-FU) plus folinic acid (FA, also known as leucovorin, LV) in combination with irinotecan (FOLRIRI) or oxaliplatin (FOLFOX) (46, 52). Regimes may also include cytotoxic drugs capecitabine or raltitrexed, (37, 53), with the combination of capecitabine and oxaliplatin (XELOX) as a common adjuvant chemotherapy (15). As described above, patients with advanced CRC may also have treatments including monoclonal antibody (mAb) targeted anti-angiogenic agents [(anti-vascular endothelial growth factor (VEGF)], such as bevacizumab (Avastin) (41, 54, 55) or anti-EGFR antagonists cetuximab (Erbix) or panitumumab (Vectibix) for indicated *KRAS* wild-type mCRCs (44, 45, 52, 56, 57). Unfortunately, a predictive marker of EGFR-inhibitor therapy is the presence of active mutations in *KRAS* or *BRAF* (V600E), in that those CRC sufferers do not respond to their therapeutic effect (58, 59). Novel antiangiogenic drugs, such as regorafenib (a novel multikinase inhibitor) and aflibercept (Zaltrap; a recombinant protein inhibitor of VEGF), have also been recently licensed by Health Canada in 2013 and 2014, respectively. Approved for the treatment of patients with mCRC, regorafenib is reserved for those who have been previously treated with fluoropyrimidine-based chemotherapy, oxaliplatin, irinotecan, an anti-VEGF therapy, and anti-EGFR therapy (60). The use of aflibercept is approved for use in combination with

Table 3. Predictive and prognostic biomarkers for biological therapy in mCRC

Biomarker	Prevalence	Available evidence	Predictive and prognostic value
<i>KRAS</i> mutations	40%	Conclusive	Negative predictive biomarker for anti-EGFR mAbs
		Insufficient	Predicts poor prognosis, but not an independent prognostic factor
<i>BRAF</i> mutations	10%	Substantial	Prognostic marker for poor outcome
		Insufficient	Potential predictive marker for resistance to anti-EGFR mAbs
<i>NRAS</i> mutations	3%-5%	Insufficient ^a	Potential predictive marker for resistance to anti-EGFR mAbs
<i>PIK3CA</i> mutations	15%-20%	Insufficient ^a	Potential predictive marker for resistance to cetuximab (exon 20 mutations) Potential prognostic marker for poor outcome
<i>PTEN</i> (loss of expression)	20%-40%	Insufficient ^a	Potential predictive marker for resistance to cetuximab Associated with activation of the PIK3CA pathway and adverse disease outcome
<i>P53</i> mutations	1%-5%	Insufficient ^a	An independent predictive factor for cetuximab benefit Not prognostic
Epiregulin, amphiregulin (high expression)	50%-60%	Insufficient ^a	Associated with resistance to anti-EGFR antibody therapy and adverse clinical outcome
VEGF-D	40%-75%	Insufficient ^a	Potential predictive marker for response to bevacizumab
VEGF-A	nd	Insufficient ^a	Not predictive of response to bevacizumab

Modified from Luo and Xu, 2014 (61)

^aInsufficient: The current clinical evidence cannot definitively demonstrate that the biomarker has predictive or prognostic value in mCRC. nd, not determined.

FOLFIRI, for patients with mCRC that are resistant to or progressed following an oxaliplatin-containing regimen (42, 60). The potential treatment combinations have been recently compiled in an extensive review by Schmoll *et al.*, highlighting the benefits of an overall personalized patient approach when defining treatment regimens (15).

Due to its prevalence and preventative nature, CRC has been a focus in the field of oncology; though much progression hindered by the broad range of its stages at diagnosis, complexity of progression, heterogeneity, and diversity among patients. Optimal treatment choice for an individual highly depends on the disease extent and localization, overall tumour biology, and ultimately, considerations for sustaining quality of life while enabling long-term survival (15). Toxicity and lack of tumour specificity are the most important limits of conventional approaches. Evidence from the widening range of available tailored regimens, or those in development, advocates that the use of personalized medicine techniques will remain fundamental in how CRC, and cancer in general, will be treated in the future (15).

1.3 Cancer immunology: immunosurveillance and immunoediting

The concept that arising nascent malignant cells are recognized and eliminated as a function of the immune system has been a dynamic debate in tumour immunology since its original proposal in 1909 by Ehrlich (62), later formally designated as the theory of cancer immunosurveillance by Burnet and Thomas (63, 64). However, in the mid-20th century, this concept remained controversial with lack of sufficient evidence in some tumour-bearing models (65). Over the past two decades, this concept has seen a resurgence of interest and with extensive work and advancements in the experimental field of tumour immunology, there is now a much broader understanding of the interactions between the immune system and tumour cells. As such during this integral time, according to a recent review by Mittal *et al.* (2014) (66), the long-lasting dispute of the immune system effects on tumour development has diminished with clear evidence that intact immunity can, in fact, have three contradictory complex functions: facilitating cellular transformation, prevention or control of tumour development, and influence on the immunogenicity of tumours (66). With recognition that immunosurveillance

represents only one part of a broader process, this concept was refined to accurately capture the dynamic process, termed ‘cancer immunoediting’ (67, 68). This theory includes the dual role of the immune system in the active elimination of tumour cells but also highlights its importance in tumour-shaping and promoting tumour outgrowth.

Overall, the immunogenicity of developing tumour cells can be shaped by the immune system. This occurs most notably by adaptive immunity (particularly T cells), but recent evidence suggests that innate immunity, such as natural killer (NK) cells and M1 macrophages, to some degree, also contribute to this editing process (69). A fundamental principle in this process of immunological destruction or sculpting of a developing cancer is the T-cell recognition of tumour antigens (70). Indeed, T cell-dependent immunoselection has been demonstrated as one crucial mechanism of cancer immunoediting, allowing the outgrowth of less immunogenic tumour cells that lack strong antigens, as a result of either reduced expression or presentation on major histocompatibility complex (MHC) class I (MHC I) (70-72). Additionally, the evidence for immunoediting is not only restricted to tumour-bearing animals, but has also been clinically observed in human patients receiving targeted vaccine immunotherapy (73, 74).

With the complex progression from immune surveillance to immune escape, cancer immunoediting comprises of three proposed sequential phases: elimination, equilibrium, and escape (67, 68, 75, 76). As a hallmark of the original immunesurveillance concept, the elimination phase is a process in which innate and adaptive immunity cohesively detect and destroy developing tumour cells, prior to clinical appearance. In the equilibrium phase, some tumour cell variants may not be entirely eliminated and the immune system maintains the tumour in a state of ‘functional dormancy’ in which the balance between anti-tumour (*e.g.* interferon [IFN]- γ , interleukin [IL]-12) and tumour promoting cytokines (*e.g.* IL-10, IL-23) in the tumour microenvironment and the adaptive immunity controls the growth of clinically undetectable, occult tumour cells. Due to constant immune pressure however, some tumour cells may undergo genetic and epigenetic changes (immunoselection), and begin evolving mechanisms that resist immune recognition such as antigen loss or expression deficiency, or induce immunosuppression, such as upregulation of programmed death-ligand 1 (PD-L1).

During the final step, the escape phase, progressive growth of edited tumour cells presents as clinical disease after the immune system fails to restrict the tumour cell population. Tumours may escape by a variety of complementary mechanisms of immunosuppression and tolerance, often exhibited simultaneously. This can include reduced immune recognition (*e.g.* loss of MHC I or tumour antigen expression), increased resistance or survival (*e.g.* upregulation of anti-apoptotic molecules), or establishment of a complex immunosuppressive microenvironment (*e.g.* VEGF, transforming growth factor [TGF]- β expression, induction of immunomodulatory molecules indoleamine-2,3-dioxygenase [IDO], PD-L1, T cell immunoglobulin mucin-3 [TIM-3]). Importantly, escape from immune control is now recognized to be one of the ‘hallmarks of cancer’ (77). Extensive work has been undertaken to elucidate the mechanisms involved in cancer immunoediting and reviewed in great detail (66, 71, 76, 78).

CRCs are collectively known to be able to manipulate and evade the immune system with increasing evidence that immune cells have an important role in tumour development and metastasis. Efforts to evaluate these mechanisms are continually ongoing [reviewed in (79-82)], some of which will be highlighted. CRC, among other solid tumours, contain a diverse subset of leukocytes, including both myeloid- and lymphoid lineages. Notably, immunogenicity of CRC tissues was demonstrated with increased activation, cytotoxic activity, and functional reactivity of tumour-infiltrating T lymphocytes (TILs) correlated with the presence of systemic functional tumour antigen-reactive T cells (83). However, the proportion of the activated tumour-associated T lymphocytes decreased significantly with higher tumour stage and was inversely correlated with the overall stage of the tumour (83). In another study, while adjacent normal mucosa contained normal levels of NK cells, impaired migration of these cells was apparent during tumour development. These cells were largely scarce within CRC tumours, despite high local tumour chemokine levels that was also independent of human leukocyte antigen (HLA) class I expression (84). While the role in CRC remains controversial, tumour-associated macrophages (TAMs) play an overall role in CRC progression. TAMs can both promote immunoselection by further inducing an inflammatory response (M1) or in response to immunosuppressive cytokines, generate a tumour-promoting TAM (M2). These TAMs

can secrete a variety of growth factors including epidermal growth factors (EGF), TGF- β , VEGF, and proteolytic enzymes such as matrix metalloproteinases that can degrade collagen of basement membranes, supporting the movement and metastasis of tumour cells (79).

Immune escape of CRC has also been closely associated with the establishment of a microenvironment that actively suppresses anti-tumour immunity. A prominent increase of myeloid-derived suppressor cells (MDSC) (characterized as Lin^{-/low}HLA-DR⁻CD11b⁺CD33⁺) was identified both in tumour tissue and systemically when compared to a healthy population and correlated with tumour stage and metastasis. With further analysis *ex vivo*, these cells were able to inhibit the proliferative function of autologous T cells (85). Regulatory T cells (Tregs) have a complex role in CRC that may be dependent on the tumour type and stage; however, Tregs are in general associated with interference of anti-tumour immune responses, but their presence seem to correlate with a favourable prognosis (80, 81, 86). Although it is clear that an enhanced number of the tumour infiltrating T cells, among the other T cell subsets, express FoxP3⁺ (87), a hallmark marker of Tregs, the contributory role remains unsettled and paradoxical within CRCs (86, 88). In addition to immune cell suppression within the microenvironment, CRC evasion has also been associated with the pro-tumour inflammatory responses, in particular IL-17, shown to increase inflammation and promote carcinogenesis in some tumours (89), as well as increased IL-6 expression has correlated with advanced stages of CRC and decreased survival (90). Observed within the tumour microenvironment of tumour-bearing mouse models of liver metastasis, high expression of IL-10, TGF- β , and TGF- α were associated with enhanced tumour growth (79, 82). Lastly, CRC tumour cells can actively suppress the immune response by downregulation or reduced expression of MHC I (91), and upregulation of PD-L1 (92).

Overall, based on the current knowledge and ever widening field of cancer immunology, in consensus, an important obstacle to overcome when treating cancers is tumour immunosuppression and tolerance (93).

1.4 Immunotherapy for the treatment of cancer

Cancer immunotherapy collectively refers to a number of intended strategies to harness and manipulate immune-mediated mechanisms to specifically target cancer for stabilization or eradication (94). The concept of immunotherapy, although increasingly prominent over the past two decades, has been well documented for over a century. In 1881, a young surgeon in New York, Dr. William Coley, initiated efforts to reproduce the observed spontaneous remissions of sarcomas in patients whom had developed erysipelas, an acute bacterial infection commonly associated with group A *Streptococcus*, by administering intratumoural injections of live or heat-inactivated *Streptococcus pyogenes* and subsequently, mixed with *Serratia marcescens*, later known as ‘Coley’s Toxin’ (95). Coley speculated that the infection localized around the tumour site would induce a direct cytotoxic reaction and as a secondary event, lead to regression, and even cure, of a malignant disease (95). The first streptococcal culture injection treatment encouragingly resulted in the extensive necrosis of an inoperable tumour and a disease-free outcome for eight years (96, 97). However, subsequent clinical responses remained variable from patient to patient, attributed primarily to disease heterogeneity and infection severity among patients, Coley also importantly noted that injections in a remote anatomic site could result in impressive tumour responses. From this, he concluded that even a systemic response to an infection, though mechanistically unclear, resulted in tumour destruction (95).

Following forty-years of treating a variety of malignant diseases, successes were sporadic, difficult to reproduce (98), and were controversial among clinicians. One notable exception however is the further application of this theory in intravesical injection of Bacillus Calmette-Guérin (BCG), prepared from *Mycobacterium bovis*, for treatment of superficial bladder cancer after surgical resection, which has shown to prolong patient survival and remains an acceptable treatment today (94, 99). During this period of time however, oncologists, excluding the BGC application, continued to rely heavily on surgery, and increasingly, on effective new emerging methods, such as radiation therapy and eventually chemotherapy. Due to the risks associated with administering infectious agents to already weakened cancer patients, Coley’s strategy was never fully embraced

and became generally disregarded until the middle of 20th century; a present irony given the trauma associated with the treatments that were becoming common practice (94). Cancer immunotherapy applications began to re-emerge as *in vivo* chemical inducible tumour models were developed, allowing for readily accessible testing of various cancer treatments (99).

Today, dramatic advances in the field of cancer immunotherapy have been made, with several broad therapeutic strategies now recognized. These approaches comprise of cancer vaccines, adoptive T lymphocyte transfer, immunomodulatory/immune check point blockade, and antibody-based therapies. In the subsequent sections, each treatment avenue will be introduced, with emphasis on antibody-based therapies, in addition to summaries of potential avenues directed specifically for CRC. It is recognized that the great breadth of knowledge that has developed within this field to date is beyond the scope of the purposes for this discussion, but have been comprehensively reviewed elsewhere (94, 99-102).

To broaden the response of cancer and to treat resistance, the combinational use of chemotherapeutic drugs has traditionally been the foundation for treatment. A significant advantage of immune-based therapies is that they can be combined rationally with these conventional treatments for optimal therapeutic effect, as well as with other emerging immunotherapies (94). For reference throughout subsequent sections, the standard clinical trial outcome and phase definitions have been included with **Appendix 3** and **Appendix 4**.

1.4.1 Vaccine therapy

Cancer vaccines aim to actively prime and stimulate the immune system against tumour cells for a specific and directed anti-tumour response. The vaccines can be designed for the prevention of tumour formation (prophylactic) or, as in the majority of those in study, the therapeutic format, for the inhibition of growing tumours and directed immune responses; both forms having the intent to generate prolonged protection (94). Antigen-based vaccines are generated through short peptides (~20-mer), with a suitable dendritic cell (DC) activating adjuvant, full length proteins with a broader epitope range, or

through viral vectors encoding tumour antigens (94). Cellular-based vaccines use either whole tumour cells or lysates (autologous or allogeneic), which contain a wide range of antigens for targeting including mutated proteins. Lastly, DC-based vaccines, where DCs are isolated from the patient, loaded with antigens *ex vivo*, activated, and then re-infused into the patient are also being explored as potential approaches, though remain in early development (94).

Despite the promising success of prophylactic vaccines used for cancers of viral origin (*e.g.* human papillomavirus [HPV]), to date, therapeutic vaccines have been less successful (94, 103). One limitation is that vaccine effectiveness relies largely on the induction and regulation of T cells, DCs, and other cell-mediated immune responses such as Treg suppression (104). Indeed, although a large number of T cells are present that are capable of recognizing tumour antigens (in preclinical models), this has been insufficient to mediate tumour regression (105-107) suggesting that T cells, in order to mediate anti-tumour effects, must be in the correct state of activation and differentiation (105). Cancer vaccines are usually administered with adjuvants, such as BCG, to enhance the immune response, and are often combined with cytokines such as granulocyte macrophage colony-stimulating factor (GM-CSF) (108, 109). Recently, co-administration of IL-2 with a short peptide derived from glycoprotein 100 (gp100), a melanocyte antigen, augmented tumour responses and progression-free survival (PFS) was prolonged (110). Ongoing advancements to understand the basic immune responses of therapeutic cancer vaccines have suggested that effective strategies may require the integration of immunomodulators through checkpoint blockade (*e.g.* cytotoxic T-lymphocyte-associated protein 4 [CTLA-4], programmed cell death protein 1 [PD-1]) to interfere with immune regulatory control to maximize the vaccine effectiveness (94, 111).

Vaccination trials for CRC have largely been tumour cell-based vaccines, consisting of irradiated autologous tumour cells (112). From meta-analyses, there was evidence of significant improvement in disease-free survival (DFS), however none in overall survival (OS). Encouragingly, in subsets of patients with resected liver metastases, there has been a significant advantage in OS and metastases-free survival (113). To date, carcinoembryonic antigen (CEA) has been the most common peptide-based vaccine in

CRC trials, however, despite supporting preclinical evidence, the results and tumour response of the studies have not remained consistent (112, 114). Alternative targeted antigens remain ongoing in clinical trials however, for further evaluation of cancer vaccines in the treatment of CRC (**Table 4**).

1.4.2 Adoptive cell therapy

In the treatment of cancer, adoptive cell therapy (ACT) is the transfer of lymphocytes bearing tumouricidal properties to the patient for directed anti-cancer effects (115, 116). A variety of cellular therapies have been incorporated into cancer treatment, including the infusion of polyclonal or antigen-specific T cells, NK cells, DC, and macrophages (M ϕ). Most recognized for transfer are the naturally occurring TILs, isolated from resected tumours of the patient, expanded in culture (with exogenous IL-2) and subsequently re-infused into the patient for therapeutic effect (115). Contradictory to other forms of immunotherapy, ACT does not rely on the *in vivo* mediation of T cell activation for tumour regression but allows for the *ex vivo* selection and expansion of high-avidity, autologous effector T cells. Importantly, developing the T cells as such also breaks tolerance to the tumour antigen, removes *in vivo* inhibitory or suppressive signals, and enables the manipulation of the recipient host (*e.g.* lymphodepletion), generating a favorable environment for effective cell transfer and engraftment (94, 115). Although limited to the identification of T cells that target tumour antigens exclusively, with this treatment approach, patients with melanoma have had marked clinical responses, experiencing tumour regressions that were durable and complete (115, 117).

Initially beneficial to patients with reactive T cells from resectable tumours, advances in genetic engineering technology of T cells has expanded ACT opportunities to patients with unresectable, solid tumours (116). Expression of specific conventional TCRs or recombinant chimeric antigen receptors (CARs) (118) in ‘normal’ T cells isolated from peripheral blood enable directed T cell effects to cognate targets. As recombinant receptors that provide both antigen-binding and T-cell-activating functions, CARs allow the immediate activation of the T cell upon recognition of the intact surface protein (118). With the use of these approaches, ACT has demonstrated discernible regressions in a

Table 4. Select representation of immunotherapy trials for the treatment of CRC currently under investigation

Treatment under clinical trial	NCT number	Phase	Study endpoints	Primary completion
Vaccines				
Study of Imprime PGG® in Combination with Cetuximab in Subjects with Recurrent or Progressive KRAS Wild Type CRC	NCT01309126	III	OS; PFS, CR, PR, OR, QoL, PK	April 2016
Gene and Vaccine Therapy in Treating Patients with Advanced Malignancies: Vaccine that targets NY-ESO-1	NCT01697527	II	Safety/Efficacy; clinical response	October 2018
Immunotherapy with CEA(6D) VRP Vaccine (AVX701) in Patients with Stage III CRC	NCT01890213	I	Safety; Number of AE	November 2015
Vaccine Therapy in Treating Patients with Metastatic Solid Tumours: Biological Agent HER2 Vaccine	NCT01376505	I	Safety/Efficacy; immune response	January 2016
Adoptive cell therapy				
Immunotherapy using Tumour Infiltrating Lymphocytes for Patients with Metastatic Cancer	NCT01174121	II	Safety/Efficacy	December 2018
CAR T Cell Receptor Immunotherapy Targeting VEGFR2 for Patients With Metastatic Cancer	NCT01218867	I/II	Safety/Efficacy; ORR	October 2018
T Cell Receptor Immunotherapy Targeting MAGE-A3 for Patients With Metastatic Cancer (HLA-DP0401+)	NCT02111850	I/II	Safety/Efficacy; safe dose	December 2016
Anti-Tumour Effects of Escalating Doses of Adoptively Infused <i>Ex Vivo</i> Expanded Autologous Natural Killer (NK) Cells Against Metastatic Cancers	NCT00720785	I	Safety; MTD, escalating dose	January 2018
Immunomodulatory molecules and immune checkpoint therapy				
Continuous Infusion of rhIL-15 for Adults With Advanced Cancer	NCT01572493	I	Safety; MTD, DLT	April 2016
Trial of NHS-IL12 in Patients With Metastatic Solid Tumours	NCT01417546	I	Safety; MTD, DLT	January 2016

Nivolumab and Nivolumab plus Ipilimumab in Recurrent and mCRC [†]	NCT02060188	I/II	Efficacy study; ORR	December 2016
A Phase I Study of MPDL3280A (anti-PD-L1) in Patients with Locally Advanced or Metastatic Solid Tumours	NCT01375842	I	Safety; DLT	April 2014 (104)
Study of Pembrolizumab (MK-3475; anti-PD-1) in Patients with Microsatellite Unstable (MSI) Tumours	NCT01876511	II	Efficacy study; PFS, ORR	June 2017
A Study of MPDL3280A Administered in Combination with Bevacizumab and/or with Chemotherapy in Participants with Locally Advanced or Metastatic Solid Tumours	NCT01633970	I	Safety; number of AE, DLT/MTD	February 2016
Anti-PD-L1, MEDI4736, in Combination with Tremelimumab in Subjects with Advanced Solid Tumours	NCT01975831	I	Safety; number of AE	December 2016
A Study of CDX-1127 (Varlilumab) in Patients with Select Solid Tumour Types	NCT01460134	I	Safety; number of AE	September 2015
Monoclonal Antibodies				
Combination Study of Urelumab (anti-4-1BB/CD137) and Cetuximab in Patients with Advanced mCRC	NCT02110082	I	Safety; number of AE	January 2017
Comparing the Efficacy and Safety of RO5520985 (bispecific anti-ANG-2/anti-VEGF-A) and FOLFOX with Bevacizumab and FOLFOX in Patients with Untreated mCRC	NCT02141295	II	Efficacy; PFS, ORR	May 2017
Ensituximab (NPC-1C), a Monoclonal Antibody Against a MUC5AC-related antigen to Treat CRC	NCT01040000	II	Safety/Efficacy; ORR, OS	January 2018
A Trial of Trametinib and Panitumumab in RAS/RAF Wild Type Advanced CRC [†]	NCT02399943	II	Efficacy; % patients with CR, PR, or stable disease	June 2018

Information gathered from the Cancer Research Institute as of 2015 (<http://www.cancerresearch.org/>); [†]Canadian locations

Study endpoint abbreviations: AE, adverse events; CR, complete response; DLT, dose limiting toxicity; MTD, maximum tolerated dose; OR, objective response; ORR, objective response rate; OS, overall survival; PFS, progression free survival; PK, pharmacokinetic; PR, partial response; QoL, quality of life.

variety of cancer indications, including melanoma, leukemia, lymphoma, and cervical cancer (115, 119-123). To date, issues remain surrounding the selection of safe targets and the scarcity of such targets, toxicity, and manufacturing complexity. Additionally, in clinical assessment, the lack of durable responses in some patients indicates that to properly direct and activate T cells within the tumour microenvironment, further interventions may be required to have lasting treatment effects (94).

While ACT has predominantly been applied to the treatment of haematological malignancies to date (124), this therapy may be beneficial for epithelial solid cancers with advancements in identification of suitable targets. Indeed, ACT clinical trials for the treatment of CRC are currently ongoing, with focus on metastatic disease (**Table 4**).

1.4.3 Immunomodulatory molecule and immune checkpoint therapy

Within anti-cancer therapies, immunomodulatory molecules can function to indirectly increase the activity of effector lymphocytes, or directly by reducing tumour growth (109). Clinical evaluations have foremost focused on systemic administration or direct tumour injection of immunostimulatory cytokines IFN- α and IL-2 (109). Independent administration of IFN- α and IL-2 has demonstrated increased survival responses in a subset of advanced melanoma and renal cell cancers (109, 125-127). Associated with low response rates in general, these treatments can also have a considerable risk of high-dose toxicity and systemic inflammation due to lack of specificity (94, 125). To date, even though IFN- α and IL-2 have been supportive therapies in particular for these cancers, as well as haematological malignancies, the mechanism and why the therapeutic effect is limited to select patients is not fully understood. With focus on T cell activation, the use of antibodies targeting known receptors (*e.g.* 4-1BB, CD27, OX40, GITR) has progressed as the next generation of immunomodulators undergoing clinical evaluations (**Table 4**) (94).

In advanced CRC patients, modest immune responses have been demonstrated with the combination of IL-2 and GM-CSF (128). Recent evaluations in mCRC patients has further indicated that chemotherapy (FOLFOX) in combination with IL-2 and GM-CSF,

has a marked improvement in overall response rate and progression free survival compared to chemotherapy alone, with a trend towards improved overall survival (129).

Cancer immunotherapy has significantly progressed over the last decade with the development of immune checkpoint antagonists. Inherently, the immune system regulates induced responses by feedback inhibitory loops to minimize tissue damage, suppress autoimmunity, and maintain proper immune homeostasis. Importantly, these mechanisms control T cell responses influencing communication between T cells and antigen presenting cells (APCs) through inhibitory receptors on the lymphocytes and respective ligands, two of which are currently clinically active for blockade, CTLA-4 and PD-1 (101). Though these checkpoint receptors act through different mechanisms (130), both are expressed on activated effector T cells, and upon cognate ligand binding, reduce effector functions. In addition, CTLA-4 and PD-1 (among other checkpoint receptors, such as lymphocyte-activation gene [LAG-3] and TIM-3) are highly expressed on Tregs but contrary to effector cells, ligand binding enhances Treg proliferation and function, promoting the suppression and attenuation of effector cells (101, 131). Predominately, antibody-based therapies have been used for directed blockade at these immune checkpoints.

Extensively studied for the role in T cell responses, CTLA-4, as a key negative regulator of CD28-dependent responses, functions by binding members of the co-stimulatory B7 family of accessory molecules on APCs required for T cell activation, and thereby inhibits further activation and expansion (132). Ipilimumab, a mAb to CTLA-4, as well as effectively blocking the negative regulation of this receptor, also down-regulates the immune suppressive function of Tregs, facilitating anti-tumour effects of T cells and limiting Treg activity in tumours (131, 133-135). In a pivotal phase III trial, administration of ipilimumab provided a significant improvement in overall survival (136) for advanced metastatic melanoma, granting its clinical approval by the Food and Drug Administration (FDA) in 2011 and by Health Canada in 2012, and is arguably one of the most important developments for cancer immunotherapy to date. In a long-term follow-up, ipilimumab has shown a durable complete response, and potentially curative tumour regression in a subset of treated melanoma patients (133, 137). Blockade of

CTLA-4 has since been undergoing further evaluation in numerous clinical settings, including mCRC (NCT02060188) (138).

Another approach receiving some clinical validation is targeting immunosuppression at the tumour site in addition to immune cells (94). PD-1 is expressed predominantly on T cells (including Tregs) after induction, but can also be expressed on B cells, monocytes, natural killer T (NKT) cells, and some DCs (139, 140). Upon binding with its ligands PD-L1 or PD-L2, which are expressed by potential target cells and can also be upregulated in a variety of cancers (141, 142), the T cells are rendered unresponsive (140). Duly summarized in Ohaegbulam *et al.* (143), several mAbs to PD-1 or PD-L1 have been clinically studied in Phase I trials and continue to be evaluated further either as a monotherapy or in combination. Of these trials, this strategy for immunomodulatory therapy has been well tolerated with impressive response rates and durability in melanoma, non-small-cell lung carcinoma (NSCLC), and renal cell carcinoma (RCC) (143). Currently, a PD-1 blocker (Nivolumab) is in clinical trials involving mCRC (NCT02060188) and similarly, studies are also proceeding using an anti-PD-L1 blocker in refractory mCRC as a single agent (NCT01375842; NCT01876511) with early responsive results (144) or in a multimodal approach with chemotherapy and bevacizumab (NCT01633970) or tremelimumab (anti-CTLA-4; NCT01975831) (**Table 4**).

1.4.4 Antibody-based therapy

Over the past two decades, antibody-based therapy for cancer has become well recognized and for patients with haematological malignancies and solid tumours, one of the most successful treatment strategies (145). Soon after the discovery of antibodies in the late nineteenth century, Paul Ehrlich described a ‘magic bullet concept,’ where drugs directly proceed to their intended structural targets (146). Targeted medicine, in his proposed theory, should efficaciously defend against invading pathogens (including cancerous cells) but remain harmless to healthy tissues (146). With clinical controversy however, this approach received little value until the ability to generate mAbs with advancements in hybridoma technology was described in 1975 by César Milstein and

Georges Köhler (147). In light of these developments, the search for cancer-specific antigens was initiated with efforts focused on identifying suitable surface structures, a challenge that still persists today (145). This family of molecules, termed tumour-associated antigens, will be described further in **Section 1.5**.

In this form of immunotherapy, antibodies can function through respective responses such as mediating alterations in antigen or receptor function (agonist or antagonist functions; *e.g.* anti-angiogenic effect), modulating the immune response or environment, or directing conjugated drugs or radiolabelled compounds that specifically target TAAs (148, 149). In addition, unconjugated mAb therapies may have immunological cytotoxic effects through opsonizing tumour cells and complement-dependent cytotoxicity (CDC), triggering apoptosis, or by removal through antibody-dependent cell-mediated cytotoxicity (ADCC) (150). All of these approaches have been successfully applied within the clinic, a proportion of those for the treatment of haematological malignancies (*e.g.* targeting CD20, CD30) including both as unconjugated mAbs and for the delivery of cytotoxic drugs or radioisotopes (145). For patients with solid tumours, the most successful mAb therapies to date have been targeting the ErbB family of receptors (including EGFR, human epidermal growth factor receptor [HER]2/neu) and VEGF, demonstrating improved tumour responses and survival (145). Immune regulation by antibodies has also has remarkable success within the clinic as described in Section 1.4.3. As of early 2015 there were 31 antibody treatments (or derivatives) that were approved by Health Canada for clinical use as monotherapy or in combination, 12 of which are designated for the treatment of various specified cancers (**Table 5**).

In the development of antibody-based therapies, preclinical and clinical evaluations have revealed the importance of target antigen selection but have also highlighted the major considerations related to therapeutic mAbs, including 1) affinity and avidity, 2) the choice of antibody construct, and 3) the desired therapeutic approach (*e.g.* signaling abrogation, immune effector function). As such, antibodies have interdependent properties that can be used for molecular alteration to improve the clinical potential. Key elements may include antibody immunogenicity, size, effector function, and overall pharmacokinetics (145, 151).

Table 5. Antibody therapies approved by Health Canada for medical use in the treatment of cancer

Name	Target	Source	Approval for indication^a	Proposed mechanism
Alemtuzumab; Campath	CD52	humanized from rat, IgG1 mAb	Second-line therapy for CLL	targets CD52 on the surface of mature lymphocytes for elimination
Bevacizumab; Avastin	VEGF-A	humanized from mouse, IgG1 mAb	mCRC; unresectable, metastatic or recurrent NSCLC; glioblastoma after relapse or disease progression	angiogenesis inhibitor
Brentuximab vedotin; Adcetris	CD30	chimeric (mouse/human), IgG1 mAb	Relapsed or refractory HL and sALCL	antibody-drug conjugate
Catumaxomab; Removab	EpCAM and CD3	rat/mouse hybrid mAb; trifunctional	management of malignant ascites with EpCAM-positive carcinomas where standard therapy is not available or feasible	elicits immune reaction by binding EpCAM ⁺ cells to CD3 ⁺ cells and Mφ, DC or NK cells (Fc receptor)
Cetuximab; Erbitux	EGFR	chimeric (mouse/human), IgG1 mAb	EGFR-expressing metastatic CRC when used in combination with irinotecan in patients with non-mutated KRAS	competitive antagonist to EGFR; inhibits growth signals
Ipilimumab; Yervoy	CTLA-4	human, IgG1 mAb	unresectable or metastatic melanoma in patients who have failed or do not tolerate other systemic therapy	prevents inhibitory mechanism to allow T lymphocytes to function
Obinutuzumab; Gazyva	CD20	humanized from mouse, IgG1 mAb	CLL in combination with chemotherapy	targets B cells (CD20) for elimination
Panitumumab; Vectibix	EGFR	human, IgG2 mAb	refractory EGFR-expressing metastatic CRC in patients with non-mutated KRAS	competitive antagonist to EGFR; inhibits growth signals

Pertuzumab; Perjeta	HER2/neu; dimerization domain	humanized from mouse, IgG1 mAb	HER2-positive metastatic breast cancer; in combination with trastuzumab and docetaxel	inhibits dimerization of HER2 receptor preventing growth
Rituximab; Rituxan	CD20	chimeric (mouse/human), IgG1 mAb	B-cell non-HL, resistant to chemotherapy regimens	targets B cells (CD20) for elimination
Trastuzumab; Herceptin	HER2/neu; subdomain IV	humanized from mouse, IgG1 mAb	HER2-positive metastatic breast cancer	interferes with the HER2/neu receptor preventing growth
Trastuzumab emtansine; Kadcyla	HER2/neu; subdomain IV	humanized from mouse, IgG1 mAb	HER2-positive metastatic breast cancer	antibody-drug conjugate

Information gathered from Health Canada Drug Product Database (www.hc-sc.gc.ca) as of May 2015.

^aCancer abbreviations: CLL, chronic lymphocytic leukemia; CRC, colorectal cancer; HL, Hodgkin's lymphoma; NSCLC, non-small cell lung cancer; sALCL, systemic anaplastic large cell lymphoma

Traditionally, murine mAbs were developed for therapeutic use and were first to be tested clinically; however, these mAbs are restricted by several factors (152-154). These mAbs are highly immunogenic, have a short-half life in humans, and as a result, are also inefficient at eliciting human effector functions (153). In particular, a major limiting factor due to the murine structure of the mAb, is the induction of human anti-mouse antibody (HAMA) response. After a first dose, administration can generate a strong response in up to 50% of patients, and >80% with repeated doses (153, 155, 156). Such responses can cause rapid clearance or direct neutralization of the administered mAb, compromise therapeutic efficacy and prevent further dosing or induction of systemic toxicity stemming from a requirement of high doses for effective treatment. In severe cases, typically associated with repeated intravenous administration, 'serum sickness' from immune complex formation can lead to an anaphylactic response (155). The current success of therapeutic mAbs can be attributed to the development of chimeric and humanized mAbs by recombinant technology, and later fully human mAbs (**Figure 1**). Using these mAb strategies demonstrates reduced immunogenicity, a longer half-life, and can promote human effector functions (157-160) and are now the preferred technologies for developing antibodies as therapeutics. Chimeric antibodies are engineered by joining the antigen-binding variable domain (Fv) of a murine mAb to the constant domains of a human antibody (161, 162). Humanized antibodies are generated by grafting the antigen-binding complementarity determining region (CDRs) from a mouse mAb within a human mAb (163, 164). To create a high-affinity humanized mAb however, the transfer of one or more additional residues from the framework regions (FRs) of the parental mouse mAb is generally required (165). High-affinity fully human antibodies are customarily derived from phage display libraries (166-168) or by hybridoma technology using transgenic mice that express human immunoglobulin (Ig) genes (169-172).

In addition to overcoming immunogenicity and systemic clearance, to gain exposure to the intended target antigen, the mAb must also overcome capillary extravasation, movement from the capillaries into the tumour tissue (173) and high interstitial pressure gradients, in particular for solid tumours (174, 175). As such, distribution of mAbs within the tumour is commonly heterogenous, even perivascular, after intravenous

Figure 1. Humanization of therapeutic antibodies for reduced immunogenicity

Schematic illustration of antibodies developed from murine origin to human to reduce immunogenicity that is applied for use in therapies. Antibodies used include fully murine mAb, chimeric mAb, where the only the variable region is murine (65% human), humanized mAb, where only the CDR loops are murine (>90% human), and fully human mAb. A generic suffix designates the form of antibody as listed. Fc indicates fragment crystallizable region (constant domain); Fab, antigen-binding fragment; ABS, antigen binding site; C_H, heavy chain, constant domain; C_L, light chain, constant domain; V_H, heavy chain, variable domain; V_L, light chain, variable domain. Figure modified from Foltz *et al.* (176).

administration (177). While this distribution can arise from heterogeneous antigen expression and vasculature, as well as tumour necrosis, it is also in part due to mAb size and antigen-binding affinity, proposed in the ‘binding-site barrier’ model where there is an inverse relationship between affinity and penetration (177, 178). This poor penetration can decrease overall efficacy and partial exposure to the intended therapeutic, increasing the risk of acquiring resistance (177). The molecular architecture of antibodies can be modified however to generate formats that varies in both size and valency (the number of antigen binding sites) (151). The growing range of alternative antibody formats can span a range of molecular weight, valency, and include multiple distinct antigen-binding specificities (**Figure 2**). The antibody building block that is most frequently used as a base in the design of non-natural formats is the single-chain variable fragment (scFv). The scFv comprises of the variable domains from the heavy and light chain (V_H and V_L) joined by a peptide linker of ~15 amino acid residues (151). Although eliminated more rapidly through renal clearance, smaller antibody fragments, like scFv, extravasate more efficiently than IgG, and diffuse more readily within tumours (151), characteristics that may be suited in particular for clinical imaging. Antibody fragments also offer the potential to avoid fragment crystallizable region (Fc)-dependent effector functions, reducing the severity of a HAMA response and can show a range of pharmacokinetic properties (151). While a reduction in distribution is characteristic of a full mAb, this form is commonly favoured for its long half-life, clearly demonstrating that each format can have opposing factors limiting success and that the design consideration can be dependent on a number of factors, including desired biological potency, the targeted tumour, and overall clinical application (179).

Similar to the choice of antibody fragment size, the effector function of the antibody can also be considered for alternation based on the target antigen, therapeutic strategy, and clinical setting (179). While increasing effector functions such as ADCC and CDC may increase therapeutic efficacy for some interventions, in others, prevention may be desired to reduce unnecessary side effects or toxicity. By mutational analysis and computational design methods, the interactions between IgG molecules and various Fc-gamma receptors (Fc γ R) for activation (*e.g.* Fc γ RI, Fc γ RIIa, Fc γ RIIIa and Fc γ RIIIb) and inhibition

Figure 2. Recombinant antibody formats for targeted therapy

A selection of possible recombinant antibody formats represented as a schematic illustration and relative approximate size (kDa). Depicted are **A)** full mAb (IgG), **B)** building blocks for antigen-binding reformatting, **C)** possible reformatted antibodies to alter size and include multivalent platforms, and **D)** multi-specific antibody options for targeting multiple antigens. Fc indicates fragment crystallizable region (constant domain); Fab, antigen-binding fragment; ABS, antigen binding site; C_H, heavy chain, constant domain; C_L, light chain, constant domain; V_H, heavy chain, variable domain; V_L, light chain, variable domain.

(FcγRIIb) has enabled the engineering of the Fc region to modulate effector functions (180). Relatedly, the regulation of serum IgG concentration has been investigated to increase (or decrease) the terminal half-life of IgG through tailoring of the interaction with FcRn, a receptor known to protect IgG from degradation (181). Lastly, the majority of currently developed unconjugated mAbs are based on human IgG, nearly all containing the IgG1 isotype. With the intent to increase mAb diversity and to develop mAbs that are often inefficient at supporting effector function, the use of classes IgG2 and IgG4 have been of interest, based on the distinct structural and functional properties (151, 182).

Stemmed from the wide range of antibody formats, the repertoire of antibody-based therapeutics is continually being expanded and presented with novel functions by conjugations and genetic fusions, including enzymes, toxins, drugs, and radioisotopes (183). A notable contribution has been bispecific antibodies, designed to bind two different epitopes, invariably on two different antigens. Most widely used for delivering immune effector cells to tumours, the single chain bispecific T cell engaging antibody (BiTE) concept allows for a convenient approach that engages both the activation of the effector cells, most commonly the T cell receptor (TCR) (anti-CD3) and an antigen on the tumour cell surface, redirecting and localizing cytotoxic lymphocytes at the tumour site (94, 184).

Even with optimal development strategies, antibody-based therapies are still limited by irregular bidistribution of the targeted antigen or receptor, accompanied by target heterogeneity, presence or development of mutations, or downregulation of expression (145). The persisting major clinical challenge is to determine therapeutic efficacy of the antibody or conjugate as a safe agent while ultimately minimizing toxicity of normal cells.

Clinically, the most successful biologic therapies, and the only approved for mCRC to date, have been with the use of mAbs (114). As mentioned in the standard treatments of CRC (**Section 1.2.2**), bevacizumab, alfilbercept, cetuximab, and panitumumab have all been approved for medical use in mCRC, and demonstrate overall clinical benefit.

Bevacizumab, a humanized antagonist mAb directed against VEGF, blocks angiogenesis and also plays a role in immune modulation through the Fc region. Similarly, aflibercept is a recombinant protein made of human VEGF receptors 1 and 2 fused to the human Fc portion, to sequester circulating VEGF and prevent activation of receptors. Cetuximab is a human/mouse chimeric antibody directed at extracellular EGFR, blocking activation of receptor-associated kinases that result in inhibition of cell growth, apoptosis, and has been shown to increase the effects of chemotherapy (185, 186). Lastly, as an additional mAb to EGFR, panitumumab is a recombinant human mAb and has similar anti-tumour effects compared to cetuximab. Of important note however, EGFR-specific Abs are restricted to only patients that have wild-type *KRAS*, as those with mutations do not exhibit improved responses, disease control, or survival (58, 187). Currently there are many investigational mAbs in clinical trials, those that are expected to generate an anti-tumour response by ADCC, augment T cell responses or further inhibit angiogenesis (**Table 4**)

1.5 Tumour-associated antigens

Traditionally, the development of an immunotherapy begins with the identification of a suitable cancer target, collectively known as tumour-associated antigens (TAAs) (188). TAAs are molecules that are selectively expressed and/or accumulated by tumours as a result of genomic instability that can generate genetic mutations, translocations, or misregulation as the tumour develops. As targets, ideally the TAA is displayed homogeneously on the surface of the tumour cells, but minimally expressed in normal tissues and serum (189). Although TAAs are heterologous in nature, several non-viral families are now characterized by their expression pattern as unique, overexpressed/accumulated, cancer-testis (CT), and differentiation antigens (190, 191).

Unique antigens, also referred to as neo-antigens, arise from chromosomal aberrations such as mutations, splicing and/or translocation in normal genes but are often characteristic for an individual tumour (*e.g.* mutated *KRAS*, *BRAF*) (190). Antigens that are overexpressed or accumulated by a tumour are often also widely expressed by normal tissues, but at a comparatively lower level (*e.g.* epithelial cell adhesion molecule

[EpCAM], Her2/neu). CT antigens are characterized by epigenetic alterations that induce expression of otherwise silenced genes, of which, only cancer cells and adult reproductive tissues primarily testis and occasionally placenta characteristically express (*e.g.* MAGE family, NY-ESO-1). Lastly, differentiation antigens are commonly shared between tumours and have restricted expression on normal tissues, typically of the same lineage. This family includes oncofetal antigens, where normal expression is generally limited during fetal development but is upregulated in adult tumour cells (*e.g.* alpha-fetoprotein [AFP], 5T4) (190, 191). TAAs encoded by tumourigenic transforming viruses (*e.g.* HPV E6/E7) can also be characterized by abnormal protein expression, termed oncoviral antigens (190, 191). Although the families of TAAs are characterized, it should be noted that these categories are not mutually exclusive and tumour antigens may fall across categories (191).

In general, methods for TAAs identification include detection by screening expression cDNA libraries from human solid tumours with sera of the autologous patients (*e.g.* SEREX) (192), screening of trophoblasts and cancer cells for shared antigenic characteristics, though not currently frequently used (193, 194), and most common, reverse immunology aiming to identify TAAs that are defined by T cell specific recognition (195). A selection of TAAs recognized by T cells derived from CRC patients is summarized in **Table 6**. This group of TAA molecules is ever expanding and is commonly evaluated for use in diagnosis, to follow treatment of tumours, or as a target for developing immunotherapeutics.

1.5.1 5T4 oncofetal antigen

The 5T4 oncofetal antigen, also designated as trophoblast glycoprotein (TPBG), is a cell surface glycoprotein normally found on trophoblasts, the outermost interfacing cell type within the placenta between the fetus and mother, but has restricted expression on normal adult tissues (196). The protein was originally identified by Hole and Stern when searching for shared surface molecules of human trophoblasts and cancer cells, that,

^c This peptide encompasses the glycine (G) to aspartic acid (D) mutation in position 12 of the KRAS protein; the mutated amino acid is underlined and typed in bold

would reflect functional similarities concerned with growth, invasion, and immunosurveillance that allow for fetal or tumour survival within its host (194). As such, human 5T4 was first defined by mouse mAbs, raised from purified glycoproteins from human syncytiotrophoblast microvillous plasma membranes (STBM), the outer epithelial layer covering the villi of the placenta. Comparative tissue screening established that the 5T4-targeting mAb detected antigen expression by different tumour cells but only low levels in normal tissue epithelia (194, 196). Subsequently, 5T4 has been identified on an array of carcinomas including cervix (197), colorectal (198-200), gastric (201, 202), lung (203, 204), oral (205), ovarian (206), prostate (207), and renal carcinomas (208). Further, as this protein remains membrane-bound and is not cleaved, there is no evidence of circulating 5T4 antigen (209).

Moreover, 5T4 has been specifically associated with metastasis in CRC (199), and there is evidence of poorer clinical outcome for CRC, gastric, and ovarian cancer with a direct relationship between the expression of 5T4 and the stage of carcinoma (198, 201, 206). Acquired from Eisen *et al.* (209), the reactivity for 5T4 antigen revealed from collected immunohistochemical studies of patient samples demonstrated the high prevalence and distribution of this TAA across multiple cancers and stages (**Table 7**).

Despite the potential therapeutic value of 5T4, the function and molecular mechanisms of this protein remain poorly understood. However, over the past two decades, biochemical and genomic studies have provided insight that this 72 kDa (420 amino acid) single-pass transmembrane-bound protein is heavily *N*-glycosylated (7 putative sites) and is a member of the family of proteins containing leucine rich-repeats (LRR) (210-213). Recent structural analysis of the extracellular domain of 5T4 confirmed that this transmembrane protein is constructed of a multiple LRR motif and associated flanking regions, clustered in two domains separated by a short, rigid, hydrophilic core (211). The LRR motif is known to contribute directly to protein-protein interactions and is associated with a functionally diverse group of molecules (210, 214). The cytoplasmic region has been reported to interact through a PDZ-binding motif (Ser-Asp-Val), commonly involved in mediating protein-protein interactions, with the PDZ domain of

Table 7. 5T4 expression of various tumour types and stages

Cancer	Type/Stage	Reactivity^a	Summary
Breast	Mixed	56/63	85-95% of patients express 5T4
Cervix	Mixed	5/5	85-90% of patients express 5T4

^bCRC represented in Dukes' classification system.

TIP-2/GIPC, a cytoplasmic interacting protein associated with the cytoskeleton (215, 216). To date, further mechanisms of downstream signal transduction for 5T4 remain unknown. From studies focused on elucidating its role, 5T4 expression was involved with early embryonic stem (ES) cell differentiation (mouse and human) and increased cellular motility (217, 218). It has also been associated with the process of epithelial-mesenchymal transition (EMT) in ES cells (219, 220), an important process during development but also designated as a key process involved in the metastatic spread of epithelial tumours (221, 222). Overexpression of 5T4 glycoprotein showed influences on cellular morphological changes, including disruption of cell-cell contacts, reduction in adherence, and actin cytoskeletal organization (223-226).

5T4 has further been shown to modulate CXCR4 function by regulation of surface expression in differentiating ES cells, mouse embryonic fibroblasts (MEFs) and cancer cells (204, 223, 227). This facilitates an increased biological response to CXCL12-mediated chemotaxis, signaling important for cell mobilization (204, 223, 227). Both CXCR4 and CXCL12 chemokines have been associated with embryogenesis as well as with tumourigenesis in many cancers with upregulated CXCR4 expressing tumours preferentially spreading to tissues that highly express CXCL12, such as the lung, liver, lymph nodes and bone marrow (228-230). Lastly, 5T4 has been found to inhibit the Wnt/ β -catenin signaling pathway (231), a key pathway involved in embryonic development and also a major target in anticancer therapeutics (232, 233). The Wnt family of proteins is known to regulate fundamental developmental mechanisms directing cellular proliferation, cell fate determination, and tissue homeostasis (234). By acting as a feedback inhibitor of canonical Wnt signaling, 5T4 activates non-canonical, misregulated signaling, often associated with disease progression prominently found in cancers (231, 235)

Comparable to 'normal' cancerous tissues, similar 5T4 expression and function has been found in tumour progenitor cells (TPCs; also known as tumour-initiating cells [TICs], or cancer stem cells) of NSCLC. Specifically, 5T4 was associated with the undifferentiated state and the EMT of the TPCs (203, 236). From this, the therapeutic value of 5T4 is

enhanced by the ability to target the aggressive and tumourigenic populations within the tumour (TPCs) (189).

There have been extensive studies elucidating the role of 5T4 in development, and recently TPCs, and though taken together, the functional biology of 5T4 is consistent with a role in movement of cells, as summarized in a recent comprehensive review by Stern *et al.* (189), the specific function of 5T4 remains unknown. Nonetheless, 5T4 has been considered an ideal candidate for cancer diagnostics and/or as a target for cancer immunotherapy, with widespread tumour expression and a link to a tumour progenitor cell phenotype (237). These characteristics have driven the development of 5T4-based therapeutics and indeed, there are currently three 5T4-targeting agents evaluated with clinical development.

Firstly, efforts to generate a vaccine using a modified vaccinia virus Ankara (MVA) encoding human 5T4 (designated TroVax) has induced an anti-tumour immune response with 5T4 epitopes recognized by T cells in preclinical cancer models (238, 239). A succession of Phase I or II clinical trials in CRC, prostate, and RCC (including in combination with chemotherapy or cytokine treatments) has established this vaccine in safety, tolerability and vaccine immunogenicity, as well as for optimal dose and route of vaccination [reviewed in (237)]. This vaccine is presently in on-going evaluations for ovarian carcinoma in Phase II clinical trials (NCT01556841). A number of targeted based therapies have also become active in development, some of which have compelling representatives to support clinical advancement. These include guiding chemotherapies as antibody-drug conjugates (ADC) (240, 241), and activation of immune effectors as tumour-targeted immunotoxins (209, 242). The 5T4-targeted ADC (A1-mcmMMAF; PF-06263507) had potent targeted anti-tumour responses in preclinical models, including primates, with limited non-specific exposure and low toxicity that was well tolerated (241). Recently terminated from Phase I clinical trials (NCT01891669), an early report noted that trial completion was not due to any safety concerns, but as a result of the program sponsor's prioritization. Secondly, a 5T4-targeted immunotoxin (ABR-21760; Naptumomab estafenatox) has demonstrated preclinical therapeutic efficacy, and has completed Phase II/III clinical trials (NCT00420888) with early reports suggesting an

overall good safety profile and a clinical benefit in a subset of patients (209, 242). Thirdly, and most recent, with the sequence resolution of the mAb defining 5T4 (243), a pre-clinical research program has been initiated for evaluation of re-targeting effectors using engineered CAR T-cell therapy (244, 245) with promising *in vitro* cytotoxicity directed specifically at 5T4 expressing tumour cells (246).

1.6 Bacterial superantigens

Bacterial superantigens (SAGs) are a unique class of microbial toxin that are known to be potent activators of T lymphocytes (247-251). The term SAg was introduced to emphasize the novel immune stimulatory properties and remarkable T cell expansion of these toxins (247, 252). Since their designation, this ‘family’ of toxins has expanded extensively over the last decade, heavily revealed by bacterial genome sequencing efforts (253). These toxins are primarily produced by *Staphylococcus aureus* and *Streptococcus pyogenes* (group A *Streptococcus*), and with more than 30 distinct SAGs currently known, are also the best characterized. Although SAGs are similar in function, a general feature of these low-molecular weight proteins (ranging from 22-29 kDa) (248) is that those that are genetically distinct are also antigenically distinct (253). The biological activity of these proteins is unusually stable, being resistant to heat (despite boiling for one hour), desiccation, and in general, proteolysis and acids (such as stomach acids) (254).

Clinically, SAGs from both *S. aureus* and *S. pyogenes* have been associated with toxic shock syndrome (TSS), a toxin-mediated acute life-threatening illness. Albeit in different forms, this syndrome is a result of an elicited ‘cytokine storm’ (248, 255, 256). As noted above, these toxins are not limited to *S. aureus* and *S. pyogenes* and in fact recently, as highlighted in Spaulding *et al.*, an increasing number of reports describe staphylococci strains of animal origin as well as other beta-hemolytic streptococci, namely groups B, C, and G as producers of SAGs (254, 257). SAGs have also been reported to occur in some viruses and other microorganisms, including *Mycoplasma arthritidis*, *Yersinia enterocolitica*, *Yersinia pseudotuberculosis*, *Plasmodium falciparum*, *Clostridium perfringens*, *Candida albicans*, and *Toxoplasma gondii* (254).

1.6.1 Staphylococcal superantigens

S. aureus are bacteria that can appear as part of the human normal microbiota, but has the ability to become a capable pathogen, causing a wide range of host infections including skin and soft tissue, as well as severe invasive infections (258). SAgS produced by *S. aureus* include the staphylococcal enterotoxin (SEs), toxic shock syndrome toxin-1 (TSST-1), and related SE-like proteins (SEI) (259). Presently classified by their SAg function, SEs were formerly defined by their enterotoxin properties in the pathogenesis of staphylococcal food poisoning (249, 260). Although SAgS from *S. aureus* and *S. pyogenes* share similar structure and immune-stimulating properties, this activity is thought to be independent of the ability to activate T cells (261) and a property not associated with streptococcal SAgS (262). Currently this group of SAgS includes ten SE serotypes: A to E, G to I, R, and T (259). Although both homologous and structurally similar to SEs, SEI group of SAgS, of those evaluated, lack the emetic properties of the bona fide SEs (259). This group of SAgS presently includes serotypes J to Q, S, U, V, and X (259, 263).

A subgroup of genetically linked SEs and SEIs, most commonly including SEG, SEI, SEI-M, SEI-N, and SEI-O and two pseudotoxins compromise an operon designated as the staphylococcal 'enterotoxin gene cluster' (*egc*) (263). Compared to classic SEs, human serum levels of neutralizing antibodies against the *egc* SEs have been shown to be lower, despite their broad distribution and prevalence (264).

1.6.2 Streptococcal superantigens

S. pyogenes (group A *Streptococcus*) is a prominent bacterial pathogen that can cause a diverse range of clinical manifestations, from common bacterial pharyngitis to severe complications related to invasive infections (265). To date, eleven genetically distinct SAgS are known to be produced by *S. pyogenes*. Commonly referred to as erythrogenic toxins, these virulence factors currently include streptococcal pyrogenic exotoxin (Spe) serotypes A, C, and G to M, as well as streptococcal mitogenic exotoxin Z (SmeZ), and streptococcal superantigen (SSA) (257). Historically defined as scarlet fever toxins, streptococcal SAgS are also associated in the pathogenesis of this illness (266). Widely

recognized in clinical implications, the contribution of SAgS for bacterial welfare is largely unknown; however recent work highlights that the biological function of streptococcal SAgS may promote the initial establishment of infection in humans, as evaluated in an acute infection of the upper respiratory tract of mice expressing human MHC II molecules. Further, SAgS may exist in redundancy to avoid host anti-*SAg* humoral immune responses and overcome polymorphisms of host MHC II (267).

1.6.3 Superantigen structure and mechanism of action

SAg structures and host cell interactions have been extensively reported from numerous structural and mutational analyses extensively reviewed by Fraser and Proft (268). Though SAg molecules generally share low amino acid sequence homology, the overall protein structure is conserved among protein family members, consisting of two major protein domains: an N-terminal oligonucleotide/oligosaccharide-binding (OB) domain, and a C-terminal β -grasp motif connected through a central α -helix (269). With similar structures, SAgS also share potent immunomodulatory properties, remarkably detected with picogram (10^{-12} g) quantities (248).

SAg-mediated activation of T cells mechanistically differs from conventional T cell activation as a processed peptide presented in the context of MHC (pMHC) on APCs (**Figure 3A**), as well as from non-specific T cell mitogens (*e.g.* phytohaemagglutinin [PHA], concanavalin A [ConA]). Instead, SAgS function by engaging lateral surfaces of pMHC as unprocessed proteins (270-273), while simultaneously engaging germline-encoded regions within the variable region of the TCR β -chain ($V\beta$) (**Figure 3B**) (274-278). MHC II molecules possess two independent binding sites for bacterial SAgS: a low-affinity site on the conserved α -chain and a zinc-dependent, high-affinity site on the polymorphic β -chain (279, 280). SAg-mediated crosslinking of these adaptive immune receptors generates a 'wedge' that allows for the large-scale activation of T cells that is independent of the peptide antigen presented within MHC II. As there are ~50 functional $V\beta$ genes in humans (281, 282), and because different SAgS can often target multiple $V\beta$ s, though preferential $V\beta$ binding is displayed (280, 283), these toxins stimulate a very large percentage of exposed T cells and the subsequent release of pro-inflammatory cytokines,

Figure 3. Structural overview of a representative SAg-mediated T cell activation complex

Cartoon representations of **A)** conventional T cell activation in complex with pMHC II (284) and **B)** representative Group IV SAg (SpeC) in complex with TCR and pMHC II cross-linked by SpeC through zinc-mediated, high affinity binding site and a low affinity binding site (272, 285, 286). The ternary model of TCR-SpeC-(MHC)₂ was produced as previously described (277). In brief, the cartoon was generated by superimposing the co-crystal structures of SpeC-TCR (PDB code 1KTK) (285), high affinity binding site SpeC-MHC II (PDB code 1HQR) (272) and low affinity binding site as predicted from SEC-MHC II (PDB code 1JWM) (287). Colours are as follows: MHCII- α -chains, *red*; MHCII- β -chains, *green*; antigenic peptides, *black*; zinc atom, *magenta*; TCR V α chain, *yellow*; TCR V β chain, *grey*; SpeC SAg, *blue*.

often referred to as a ‘cytokine storm’ (e.g. IL-2, IFN- γ , and tumour necrosis factor [TNF]- α) (248). This leads to the polyclonal expansion of particular V β subsets of T cells or T cell subsets, a process known as V β skewing. Typically, in conventional T cell activation, antigens stimulate ~0.01% of naïve T cells through specific interactions as processed peptides displayed in the context of MHC II on APCs. In contrast, the aforementioned mechanism demonstrated by SAgS can stimulate >20% of all exposed T cells (248). Although SAgS do not engage MHC I molecules, these toxins do activate both CD4⁺ and CD8⁺ T cells (288), as well as in specific cases, unconventional T cell subsets such as invariant NKT cells (289) and $\gamma\delta$ T cells (290). Collectively, this activation will further lead to bystander activation of accessory cells such as NK cells (291), and the recruitment of monocytes, M ϕ , neutrophils, and DCs (248, 251, 280). Reports have also demonstrated that stimulation from evaluated SAgS can result in a dose-dependent TCR V β -specific expansion of activation-induced CD25⁺ FoxP3⁺ cells, indicative of a Treg phenotype. Though these cells express IL-10, their suppressive function remained highly cell-cell contact dependent (292, 293).

Although SAg toxins have long been recognized to induce V β -specific T cell anergy, a state of unresponsiveness to stimulation and/or deletion following activation (294-296), evidence suggests that the fate of the T cell population may be influenced by both SAg concentration and duration of exposure, and that with addition of IL-2, the anergic cells may be indeed rescued (297).

1.6.4 Superantigen classification

A phylogenetic classification scheme of the SAg exotoxins has recently been updated where SAgS from staphylococci and streptococci are placed into five evolutionary groups based on amino acid alignments (253). Within this classification, the Group I SAgS contain only one member, the evolutionary distinct TSST-1. This group contains only one MHC II binding site in the OB-fold; a low-affinity site that interacts with the α -chain of MHC II molecules (271). Lacking the proposed emetic cystine loop of SEs, this SAg indeed does not induce emesis (262), though is considered the major cause of the menstrual form of TSS (298, 299).

The Group II SAGs contain both staphylococcal and streptococcal SAGs with members commonly linked with both non-menstrual-associated cases of staphylococcal TSS [SEB; (300)] and streptococcal TSS [SpeA; (256)]. Similar to Group I, Group II SAGs contain only one low-affinity α -chain MHC II binding site as highlighted in Spaulding *et al.* (254).

The Group III SAGs are only populated by staphylococcal SAGs and although the Group II SE SAGs are often implicated as well, this Group generally contains those most commonly associated with staphylococcal food poisoning (*e.g.* SEA, SEE) (301). Unique to the Group II and III SAGs is a “cystine-loop structure” that is thought to be important for emetic activity (302), though its presence does not assure emesis, demonstrated by a lack of this activity by SpeA (262). Group III SAGs contain a low-affinity α -chain MHC II binding site as in previous groups, but also contain a second, zinc-mediated high-affinity MHC II β -chain binding site within the SAG β -grasp domain (248, 303).

The Group IV SAGs are restricted to only streptococcal members, and are characterized as having the high-affinity binding sites for MHC II molecules, as in Group III but lack the designated cystine loop and therefore are known for lack of emesis (248). Although the low-affinity MHC II α -chain interaction has not been characterized structurally, considerable evidence has indicated its presence (286, 304).

The Group V SAGs, with the exception of SpeI (and related orthologues) contain mostly staphylococcal SAGs, and are the most recent to be described and highlighted in Spaulding *et al.* (254). Further, this Group includes only SEI toxins, other than SEI. Members of Group V are predicted to contain both the high- (305) and low-affinity MHC II binding sites and lack the emetic cysteine loop (254). Interestingly, SEI is the only SAG outside of the Group II and III SAGs reported to have emetic activity, albeit comparably weak (306). Lastly, Group V SAGs are characterized by a unique, relatively conserved ~15 amino acid extension referred to as the α 3– β 8 loop (307). The evolutionary SAG Groups are summarized in **Table 8**, highlighting key structural features discussed.

Regardless of the subtle or dramatic differences within the SAG-mediated T cell activation complexes, each member within the SAG family of toxins, despite its group

Table 8. Structural features of known staphylococcal and group A streptococcal SAgS

Group	SAgs ^a	MHC II interactions	Cystine loop ^b
I	TSST-1	low-affinity site α -chain	No
II	SEB, SEC, SEG, SER, SEI-U, SpeA, SpeH, SSA,	low-affinity site α -chain	Yes
III	SEA, SED, SEE, SEH, SEI-J, SEI-N, SEI-O, SEI-P, SEI-S	low-affinity site α -chain, high-affinity site β -chain	Yes
IV	SpeC, SpeG, SpeJ, SpeK, SpeL, SpeM, SmeZ	low-affinity site α -chain, high-affinity site β -chain	No
V	SEI, SEI-K, SEI-L, SEI-M, SEI-Q, SEI-V, SpeI	low-affinity site α -chain, high-affinity site β -chain	No

Modified from Spaulding *et al.* 2013 (254) based on current phylogenetic classification scheme (253). ^a SAgS SET and SEI-X are currently not aligned amongst established evolutionally groups. ^b Presence of cystine loop, although related, is not fully predictive of emetic activity.

classification, is able to efficiently activate large numbers of T cells. Notably, the one common structural feature of all characterized SAg, with the exception of the V α -specific SEH, is the engagement of the V β CDR2 loop, which appears to be the critical determinant for V β -specificity (277).

1.6.5 Superantigens and cancer therapy

There have been significant efforts to design SAg-based immunotoxins, collectively known as tumour-targeted superantigens (TTSs), in order to artificially ‘force’ T cells to recognize TAAs in a non-MHC-restricted manner. TTSs are recombinant fusion proteins that consist of an anti-tumour antibody moiety genetically fused to a SAg (308, 309). The intent of TTSs is to treat tumours through localization and activation of the patient’s immune system at the tumour site, with particular aims to augment a cytotoxic T lymphocyte (CTL) response. Presented in **Figure 4** are the highlights from TTS preclinical and clinical developmental.

1.6.5.1 Developmental concept of ‘first-generation’ TTSs

The concept of using SAg as a targeting moiety for human CTLs was initially developed based on early studies by Dohlsten *et al.* and Hedlund *et al.* (310, 311). In these studies, MHC II⁺ tumour cells function as a receptor for members of SE SAg, wherein at pM concentrations, this complex specifically lead to subsequent triggering and lysis by CTLs; a mechanism coined SAg-dependent cellular cytotoxicity (SDCC) (310-313). As MHC II⁺ tumour cells are of minority in malignant disease and systemic T-cell activation would be expected, the general application of this treatment was limited (308).

From this concept, tumour-specific SAg emerged, originally created by coupling wild-type SEA SAg to tumour-reactive mAbs (C215 or C242) to ‘coat’ the tumour cells with TTS (mAb::SEA) (308, 314). C215 (IgG2a) and C242 (IgG1) are mouse mAbs obtained after immunization with human colon carcinoma cell line (Colo205) and are known to recognize tumour-related epitopes associated with human colon and pancreatic carcinomas, respectively (315-317). In this pioneering work, the TTSs presented as cytotoxic mediators, selectively targeting SEA-responsive CTLs, *in vitro* and *in vivo*, for

Figure 4. Developmental timeline of TTSs in preclinical and clinical evaluation.

Schematic illustration of the developmental timeline of TTSs over nearly three decades. Highlights for preclinical and clinical arms of evaluation are represented by year of publication, TTS involved, and if applicable, key facts of model or phase trial. All combinational TTS preclinical work was completed in a murine C215-B16 tumour model. References are listed within **Appendix 5**.

localization against tumour cells in a MHC II independent manner. Progression of the TTS concept lead to the assembly of genetic fusions containing wild-type SEA SAg and the antigen-binding fragment (Fab) region of the tumour-reactive mAbs, producing a recombinant protein (Fab::SEA) (309). These TTSs maintained efficient tumour targeting and T cell stimulatory properties but resulted in an overall reduction of MHC II binding (compared to native SEA) (309). Designated as SAg-mediated antibody-dependent cell cytotoxicity (SADCC), the Fab-SEA demonstrated a substantial reduction in tumour burden and improved the rate of mortality in a C215-expressing B16 syngeneic melanoma metastasis model (309, 318-322). Most notable, four daily injections of Fab-SEA resulted in 90–95% reduction in the number of metastases (321). The potential to render the immune system in a hyporesponsive state was noted with this regime (321); however, the inability to eradicate residual tumours was recovered with two repeated cycles of TTS amongst a resting period, successfully eliciting a secondary anti-tumour response and significantly prolonging survival (322). Furthermore, in a humanized severe combined immunodeficient (SCID) mouse model, reconstituted with human PBMCs and disseminated human Colo205, C242Fab-SEA treatment resulted in strong inhibition of tumour growth, reduction in overall burden, and full resolution of carcinoma in a proportion of animals (318, 319).

1.6.5.2 ‘First generation’ TTSs in clinical trials

In Phase I clinical trials for the treatment of advanced CRC and pancreatic cancer, safety was established in single dose infusion (323, 324) and escalating repeated dose regimens (325) of the Fab moiety of mAbC242 fused to SEA (PNU-214565; nacolomab tafenatox). Although transient and manageable, toxicities occurred among patients; of these adverse events, fever and hypotension were the most common and correlated with a high induction of circulating IL-2 and TNF- α (324). Rapid systemic immune activation and associated toxicities presumed to be a result of TTS interaction with MHC II containing tissues, followed by engagement of appropriate V β subsets of T cells (323-325). To avoid severe systemic toxicity, the treatment could only be given in very low amounts, limiting the initial dose range (0.01 ng kg⁻¹-4 ng kg⁻¹) and ultimately, illustrated the considerable biological activity of the TTS (323, 324).

In an accompanying repeated-dose trial, the TTS treatment was safely administered in the program (one cycle of 4 consecutive daily infusions), and though not cumulative, parallel toxicities among patients remained (325). Once more, toxicity preceded with systemic cytokine induction and adverse events further correlated with transient losses in lymphocyte subsets (323, 325). In addition to cytokine induction, the required dose for half maximal effective concentration (EC_{50}) correlated highly with the ratio of baseline circulating anti-SEA antibodies (pre-existing) and necessitated unanticipated individualized dosing (325). Laboratory and clinical findings showed no detectable HAMA responses to TTS infusions and despite the ability to bind to normal colon tissue, the TTS demonstrated no obvious organ-related side effects (324, 325).

1.6.5.3 Development of ‘second-generation’ TTSs

The first generation Fab::SEA TTSs, through the SAg moiety, still retained a considerable affinity for MHC II molecules (326), resulting in systemic T cell activation and cytokine toxicity from accumulation in MHC II positive tissues (324, 326, 327), a reported source of dose limiting toxicities (DLTs). To circumvent this response and allow for successive administration regimes, ‘second generation’ TTSs were introduced with a mutated version of SEA. Resembling other class III (SE) and IV (Spe) SAgS (253), SEA has two distinct MHC II binding sites (328, 329); one of which is low affinity and the other contains residues that co-ordinate a Zn^{2+} ion to form a high affinity binding site to the β -chain of MHC II (328, 330). Designed with a substitution at a key amino acid involved at this interface, Asp²²⁷ (328, 330), the altered SEA maintained T cell stimulatory properties and cytokine release in the presence of MHC II, albeit at a much reduced activity (>100-fold compared to wild type SEA) (328, 331). Administered at high doses *in vivo*, the tailored TTS (Fab::SEA_{D227A}) eliminated systemic immune activation and toxicity but maintained a strong T cell-dependent antitumour response in both a C215-B16 model of mice transgenic for TCR V β 3 (332), a preferential V β binding for SEA (332, 333), as well as in an anti-CD19 humanized mouse model carrying B lymphoma cells (Daudi) (334). Overall, the Fab tumour specificity replaced the initially required MHC II reactivity properties of the SAg, allowing targeting and activation of cytotoxic T cells (326, 334).

Later studies utilized a recombinant fusion of the modified SEA (Asp²²⁷) with a mouse Fab to target the oncofetal antigen, 5T4 (335, 336). While maintaining a reduced binding for MHC II through the modified SEA, this 5T4-targeting moiety had a high affinity for this tumour-restricted antigen (nM; mean K_d of 10^{-9} M) (335). This TTS resulted in ~95% reduction of tumour mass in a NSCLC model (335).

1.6.5.4 ‘Second generation’ TTSs in clinical trials

Using the treatment anatumomab mafenatox (5T4Fab::SEA_{D227A}; PNU/ABR-214936) in a Phase I clinical trial, safety and maximum tolerated dose (MTD) was established in NSCLC patients as the primary objective (337). The treatment, received as single infusions on four consecutive days, had minor tumour responses in assessable patients (66/78), defined as greater than 25% tumour regression (12% [8/66] of patients) (337). Among certain patients, DLTs were reported and fever, hypotension, and nausea remained common adverse events overall (337). The MTD ranged from 103 ng kg⁻¹ to 601 ng kg⁻¹, a relatively low dose, although a marked improvement from the TTS predecessor (337). Encouragingly from Phase II studies in RCC patients, a prolonged survival was observed compared to expected survival rates, and in particular, patients receiving the highest dose of treatment within this study lived almost double the amount of time than expected (338). The largest proportion of patients (27/43) showed stable disease and one patient (1/43) showed a partial response (PR). Notably, a large increase in patient IL-2 serum levels observed on the second day of treatment correlated positively with overall prognosis and importantly, a significantly longer survival time. From this, circulating IL-2 levels may provide a useful pharmacodynamic marker for clinical effect of this TTS (338).

Although with promising clinical trial results, many patients had pre-existing antibodies to SEA which required individualized dose-escalation TTS treatment regimens to overcome neutralizing effects of these antibodies (337). Consequently, patients with high anti-SEA antibody values were not recommended for treatment with anatumomab mafenatox in subsequent studies (337). This response remained within Phase II as an increase in titers following the first cycle were reported in a majority of patients, but this

was not further boosted by further exposure (338). Further, the murine Fab led to elevations in HAMA levels following multiple cycles of treatment (337, 338). Together, these effects lead to the requirement of relatively high doses for a measurable anti-cancer treatment.

1.6.5.5 Development of ‘third-generation’ TTSs

In parallel the initial clinical evaluation of anatumomab mafenatox, a ‘third-generation’ TTS was developed to advance the concept. The main intention was to reduce the overall immunogenicity demonstrated by the SAg moiety in predecessors and reduce the neutralizing effects of preformed antibodies in patients. Previously reported, SEA specifically had pre-existing anti-SEA antibodies in a proportion of patients (337). Additionally, as TTS treatment is most effective when given in repeated cycles (321, 322), high titers of antibodies against SEA can be developed (339).

In order to reduce antigenicity, the succeeding generation of this TTS therapeutic, naptumomab estafenatox (ABR-217620; ANYARA) was established. This TTS, like the predecessor, consists of the murine anti-5T4 Fab, but is linked to the chimeric SAg moiety, SEA/E-120, engineered in a multi-step process by Erlandsson *et al.*, resulting in a TTS with a distinct pharmacological profile (339). In addition to reduced MHC class II binding (Asp²²⁷), SEA/E-120 has structural modifications to reduce immunogenicity and decrease binding by human antibodies (339). Designed with the premise that individuals in general are reported to have lower pre-existing antibodies to SEE compared to SEA, and that SEE demonstrated low anti-tumour properties, the chimeric SAg demonstrated that ~85% of the antibodies binding the previous SEA no longer affected SEA/E-120 in preclinical studies (339). Further, this TTS formulation demonstrated a higher efficiency compared to its predecessors of inducing T cell-mediated cytotoxicity of tumour cells *in vitro*, a superior binding affinity for the target antigen 5T4, and a dramatic reduction in tumour mass with repeated administration in a humanized murine model (intraperitoneal [ip]) of human lung metastases (Calu-1) (242).

Later studies reported that multimeric naptumomab estafenatox selectively binds to, activates, and expands T cells expressing V β 7-9, including CD4⁺ and CD8⁺ subsets and

directs CTL cytotoxicity to 5T4-expressing cells despite the diminished MHC II binding and structural epitope alterations (340). Based on the succession of TTS generations and balancing the binding relationships of the TTS, it is currently hypothesized that for an optimal formulation to maximize anti-tumour effects, the immunotoxin ideally has a high affinity for the tumour antigen, low affinity for the TCR, and very low affinity for MHC II proteins; a formulation exhibited by the current TTS, naptumomab estafenatox (209).

1.6.5.6 'Third generation' TTSs in clinical trials

The latest TTS, naptumomab estafenatox, has undergone two prospective Phase I clinical trials as a monotherapy in patients with advanced NSCLC, pancreatic cancer, and RCC, and as a combination therapy [based on (341)] with docetaxel, a cytostatic chemotherapeutic drug, in patients with NSCLC (342). With the primary aim to establish the MTD, the secondary objectives were to evaluate safety profile, immunological response, pharmacokinetic parameters, and effects on disease. Within the monotherapy evaluation, naptumomab estafenatox was administered daily ($0.5 \mu\text{g kg}^{-1}$ – $27.4 \mu\text{g kg}^{-1}$) for five consecutive days, based on large animal safety/toxicology (*Macaca fascicularis*) studies [unpublished data reported in (342)] and previous clinical evaluations (anatumomab mafenatox), acknowledging the designed insensitivity to preformed anti-SAg antibodies, with select patients receiving a second or third treatment cycle. Within the combination arm, TTS doses were obtained from the monotherapy information, and docetaxel was administered as a fixed standard dose (75 mg m^{-2}) (342).

In both arms of evaluation, naptumomab estafenatox was well tolerated, with manageable treatment-related adverse events of fever, nausea, hypotension, and rigors, all pronounced during the first treatment cycle (342). Recorded DLTs associated with this TTS consisted of fever, hypotension, liver toxicity, and acute vascular leak syndrome; all patients whom had received $>20 \mu\text{g kg}^{-1}$ dose but unlike its predecessors, independent of preformed patient anti-SAg antibodies (342, 343). An immediate (3 hour) dose-dependent increase in systemic immune activation of IL-2, IFN- γ , and IL-10 plasma levels was observed with some evidence of anti-tumour activity. This included stabilization of disease in 36% (14/39) and 38% (5/13) of patients receiving monotherapy (NSCLC and RCC) and

combination therapy (NSCLC), respectively, and partial responses in 15% (2/13) of patients within the combination arm (342). Among these patients, the SAg reactive population of T cells were selectively expanded after TTS infusions, and returned to normal levels one month post-treatment, with enhancement of tumour infiltration of T cells after treatment in tumour biopsied NSCLC patients (343). Anti-SEAg antibodies were increased in approximately 50% of patients after one cycle, and although low, levels of HAMA were detected but were reported not to effect the overall pharmacokinetics of naptumomab estafenatox (mean plasma concentration half-life of ~1 h over all cycles), presumed due to exceedingly small doses compared to non-conjugated mAb-based therapies (343). Based on the IL-2 level post-administration of the TTS, unlike previous trials, sufficient drug access could be monitored and dosing for patients adjusted within this evaluation (343). Overall, naptumomab estafenatox was concluded to be safe for administration to patients with advanced malignant disease and pharmacological proof-of-principle obtained for the TTS concept (342, 343).

Based on preclinical models with TTSs and IFN- α (344), a randomized Phase II/III trial in patients with advanced RCC was conducted with naptumomab estafenatox, comparing the TTS (15 $\mu\text{g kg}^{-1}$ given 3 cycles of 4 daily intravenous [iv] infusions; MTD for RCC in Phase I trials) plus interferon- α (9×10^6 U given subcutaneous 3 \times weekly), to interferon- α alone (same dosing). Although well-tolerated and comparable to Phase I trials, early information revealed that the study did not reach the primary endpoint of OS; however, an unexpected majority of patients had high levels of pre-formed anti-SEA/E-120 antibodies, which may have contributed to suboptimal therapy (209, 345, 346). Notably, a subgroup analysis of those patients with normal anti-SEA/E-120 neutralizing antibodies and low basal IL-6, a current biomarker for immune status of the tumour microenvironment (347), demonstrated that the combinational therapy with IFN- γ may improve and did demonstrate treatment advantages in both OS and PFS (346, 348). Furthermore, preliminary assessment of the immunological responses revealed patients with pronounced IL-2 induction and T cell expansion after treatment correlated with longer OS (348). After three days of initial treatment, the total T cell population, including TTS-specific T cells, was reduced in the peripheral blood of assessed patients. However, the expansion level of TTS-specific CD8 $^{+}$ and predominately CD4 $^{+}$ T cells was

significantly higher eight days after the first treatment cycle (4 days post-last TTS infusion) (348). Preliminary reports noted a large proportion of the expanded TTS-specific CD4⁺ T cells displayed a memory phenotype (CD45RO) and were also detected in FoxP3⁻ and not FoxP3⁺ cells, suggesting that the TTS expanded T effectors cells rather than Tregs. This response was preceded with an increase of serum levels of IL-6, IL-10, and TNF- α , particularly after the first treatment cycle (4 days post-last TTS infusion) (348). Although this form of therapy may need to be patient specific (209, 346), the human data for TTS remains promising, and studies have clearly demonstrated the potential of TTSs for cancer immunotherapy. Presently, future development strategies are aimed at starting a Phase II/III with a novel combination of naptumomab estafenatox with a tyrosine kinase inhibitor (209).

1.6.5.7 Directed-cytotoxic mechanisms of preclinical TTSs

Although specific mechanisms of TTS-induced anticancer immunotherapy have not been fully elucidated, it can be speculated that the therapeutic efficacy is attributed collectively from several combination of mechanisms: 1) activation and direct lysis by T cells of TAA-expressing tumour cells, 2) suppression of tumour cell growth by secretion of cytokines and 3) recruitment of immune cells and cytokine secretion that eliminates TAA-negative tumour cell variants (**Figure 5**) (209, 349, 350).

SAGs are able to induce cytotoxicity by direct activation of CTLs (310) and induction of activated T cell cytokine release, primarily IL-2, TNF- α , and IFN- γ with subsequent activation of accessory cells such as NK cells (349, 351, 352). Consistently, initial preclinical studies report that therapeutic effects of TTS were largely associated with immune infiltration, inflammation, and activation localized to the tumour (318, 320, 322, 350, 353, 354). Predominantly present were CD4⁺ and CD8⁺ T cells, as well as a large fraction of M ϕ (354). The overall response resulted in a strong T cell-dependent direct cell-mediated cytotoxicity through apoptosis (312, 332) and a release of pro-inflammatory cytokines, predominantly TNF- α and IFN- γ (312, 313, 353, 354). Specifically reported, in a single-cell based study with SEA, the cytokines IL-2, IL-4, IL-5, IL-10, IL-12, TNF- α , IFN- γ , GM-CSF, and TGF- β were foremost produced; the

Figure 5. TTS proposed mechanism of action

TTS proposed mechanisms leading to anti-tumour effects represented as schematic illustrations. Images were modified from Eisen *et al.* (209), targeting the TAA 5T4 and based on **A)** preclinical investigations with TTSs and **B)** immunological responses observed from early analysis of clinical treatment cycles of naptumomab estafenatox (348).

majority of the TNF- α , IL-2, IL-12, and IFN- γ were made by the infiltrating human leukocytes, while the tumour cells were induced to produce IL-4, IL-10, and TNF- α (353), ultimately leading to SAg-mediated cytotoxicity. Derived primarily from CTLs, perforin-mediated lysis largely contributed to the eradication of local TAA positive cells (354, 355) and concomitantly, CD95 Fas receptor expression occurred to induce programmed cell death in the tumour cells (353).

A synergistic effect of these cytokines resulted in growth inhibition of cells (tumour suppressive), including those lacking the targeted TAA, and overall increased inflammation in the tumour area (314, 350, 353, 355, 356). IFN- γ production through CD4⁺ T cells was classified an important mediator for the overall cytostatic response, and was found to exert both direct and indirect anti-tumour effects (354). From knock-out *in vivo* studies, recruitment of cytotoxic cells and M ϕ depended on this cytokine to mediate strong tumouricidal effects (354) and effective therapy was influenced by the overall release of IFN- γ (354, 355). Preclinical work implied that both CD4⁺, as well as CD8⁺ T cells were necessary to collaborate for optimal anti-tumour effects of TTS (354). Repeated injections augmented these effects (320, 321, 350) with a strong SEA_{D227A}-induced production of IL-2, INF- γ , TNF- α , and IL-6 (326) and also resulted in more pronounced primary synthesis of macrophage inflammatory protein (MIP)-1 α (CCL3) and MIP-1 β (CCL4) at the local tumour site for immune cell recruitment (354). SAg-reactive T cells simultaneously produced high levels of IL-2 inducing expansion and sustained T cell proliferation, with accumulation within the tumour area (354). These secondary events were important for anti-tumour effects against sub-populations of cancer cells not expressing the targeted TAA (335, 354).

Mechanistically, SAgS have the potential to induce T cell anergy and deletion, predominately after a period of strong T cell activation (295); however experimental studies *in vivo* with repeated exposure of TTSs have demonstrated that the T cell effector functions were recovered after eight weeks (321, 322). Further, the potential induction of dose-dependent T cell unresponsiveness may be resolved with combination of IL-2 (357, 358) and remains, among other immune modulators, an area of study for potential combinational therapies.

Recently, clinical applications of repeated cycles of TTSs have described immunological responses, proposing a sequence of events that may lead to therapeutic efficacy (209, 348). Initial mobilization of T cells occurs immediately after administration, signified by T cell activation and increase in cytokine production (*e.g.* IL-2, TNF- α , IFN- γ) and expansion (Days 1-2). Throughout the treatment cycle on Days 3-4, full localization of the TTS occurs, encouraging further T cell infiltration, activation, cytokine production, and immune elimination (*e.g.* CTLs) of the targeted tumour cells with the elicited secondary events destroying TAA-negative bystander cells (**Figure 5B**) (209, 348).

1.6.5.8 Combinational therapies of TTSs

Clinically, TTSs have the compelling ability to also be used in combinational therapies. Early preclinical studies exhibited sustained T cell activation (CD4⁺ and CD8⁺) and an increase in IFN- γ and TNF- α production when the first generation TTS (C215Fab-SEA) was co-administered with a tumour targeted IL-2 fusion protein (357, 359). Improved therapeutic efficacy and long-term survival of the combination treatment correlated with tumour infiltration and prolonged immune response compared to either treatment alone in an established murine C215-B16 melanoma model (357, 359).

Later studies demonstrated a synergistic anti-tumour response in the C215-B16 model when the TTS C215Fab-SEA was administered in a combined treatment with IFN- α (344). This response was accompanied with heightened CD8⁺ T cell infiltration into the tumour area, enhanced induction of perforin-dependent cytotoxicity, and prolonged survival time (344). Further, when combined in a multi-cycle regimen with the cytostatic drug docetaxel, a member of the widely used conventional cancer chemotherapies, pretreatment did not interfere with T cell responses but enhanced cytotoxicity and the overall tumour therapy was significantly improved (341). When compared to monotherapies, prolonged long-term survival was synergistic and administration of docetaxel reduced the development of anti-SEA response after repeated TTS treatment (341). This preclinical work was subsequently applied to an ongoing Phase I clinical trial with naptumomab estafenatox as a combination evaluation with docetaxel with encouraging synergistic effects (342).

Immunotherapeutic modalities, such as TTS, may expand tumour antigen-specific Tregs as well as T effector cells, inducing immune suppression and diminishing expansion of effector cells (360). Increased levels of Tregs (Foxp3⁺) were reported in recent Phase II/III clinical trials after treatment cycles with naptumomab estasfenatox but interestingly were not within the TTS-specific CD4⁺ subpopulations (348). Preclinical models of this TTS in conjunction with blockade of CTLA-4, a key negative regulator of immune responses, induced a favorable shift in the ratio between T effector and Tregs infiltrating the tumour and significantly prolonged the overall CTL response and sustained augmented responses in repeated TTS cycles (361). Monotherapy of an antagonistic CTLA-4 mAb was ineffective against tumours but enhanced anti-tumour effects in tumour-bearing animals and improved overall long-term survival (361).

1.6.6 Streptococcal pyrogenic exotoxin C and immune mediator interactions

Streptococcal pyrogenic exotoxin C (SpeC) is a 24 kDa, 235 amino acid protein (362) produced by *S. pyogenes* that was first characterized in 1977 by Schlievert *et al.* (363). Clinically, SpeC has been generally associated with streptococcal TSS, a toxin-mediated acute life-threatening illness, which results from a ‘cytokine storm’ elicited by the polyclonal T-cell expansion properties of SAGs (248). SpeC has also been implicated in other toxin-mediation ailments, such as scarlet fever, but a strict association is not always detected (364).

Since its initial description, this Group IV SAG has been well-studied in terms of both structure (272, 285, 365) and functional engagement of host receptors (277, 286, 366-368). As distinct SAGs typically display unique V β T cell activation profiles (283), it was determined that SpeC preferentially binds and activates human V β 2⁺ T cells, although it is also capable of binding to V β 3, 4, 12, and 15 T cell subsets (283, 366). Indeed, a co-crystal structure of SpeC bound to human V β 2.1 chain identified extensive binding interactions of SpeC with CDR1, CDR2, hypervariable region 4 (HV4), FR3, and CDR3 of the TCR (285), and further work has elucidated its important interactions in a functional-map analysis specifically with CDR2 (277). Extensive work with SpeC has revealed that the TCR and pMHC II are cross-linked by SpeC through a zinc-mediated,

high-affinity binding site, ‘docking’ the SAg within the complex, and a predicted low-affinity binding site, two distinct interfaces interacting with MHC II molecules (272, 286, 369). The high-affinity interaction is between the C-terminal domain of SpeC and the β -chain of MHC II (272), while the low affinity interaction occurs between the N-terminal domain of SpeC and the α -chain of MHC II (286) (**Figure 6**).

Comprehensive mutational analysis has generated ‘functional’ maps that have designated critical amino acid residues of SpeC involved at each binding interface (286, 367, 368, 370). Such analysis has allowed for the development of a non-mitogenic and non-lethal SpeC molecule, that when used as a vaccine, was able to protect against a rabbit model of TSS (367). Indeed, the single Asp²⁰³ to Ala mutation in SpeC, a critical amino acid in the zinc-mediated, high affinity MHC II interaction, has also been demonstrated to dramatically reduce toxicity in a lethal model of TSS (369). A representative structural overview of the SpeC-mediated T cell activation complex, along with highlighted critical residue mutations, Tyr¹⁵ (368) and Asp²⁰³ (272, 286, 369) is presented in **Figure 6B**. This knowledge may also allow for SpeC to be engineered as a prototype SAg for future use in immunotherapy treatments of human disease, such as those directed at cancer.

1.7 Rationale and Hypothesis

In recent years it is clearly evident that giant strides have been made in the development of cancer immunotherapeutics and that it will be vital for research to continue to provide alternative treatments for such a worldwide devastating disease. In the work to be described, it was sought to expand the repertoire of TTSSs to include the first streptococcal SAg, using SpeC as the prototype. Bacterial genomic sequencing efforts over the last decade have now revealed an extensive ‘family’ of SAg exotoxins in both *S. aureus* and *S. pyogenes*. A general feature of these toxins is that genetically distinct SAgS are also antigenically distinct, and furthermore, distinct SAgS also typically display unique V β activation profiles (283). Thus, *S. aureus* and *S. pyogenes* have provided an abundance of T cell mitogens that could potentially be engineered as TTSSs for cancer therapy. Prior to this work, TTSSs had been built exclusively using members of the SE class of SAg, and SEs are also agents of staphylococcal food-borne illness, an activity

Figure 6. Structural overview of the SpeC-mediated T cell activation complex and important residues involved at binding interfaces

Cartoon representations of **A)** SpeC in complex with TCR and pMHC II cross-linked by SpeC through zinc-mediated, high affinity binding site and a low affinity binding site (272, 285, 286). **B)** Close up view showing two important SpeC residues involved in the interaction at the TCR interface (Y15) and the high-affinity binding MHC II binding interface (D203). The ternary model of TCR-SpeC-(MHC)₂ was produced as previously described (277). In brief, the cartoon was generated by superimposing SpeC-TCR (PDB code 1KTK) (285), high affinity binding site SpeC-MHC II (PDB code 1HQR) (272) and low affinity site as predicted from SEC-MHC II (PDB code 1JWM) (287). Colours are as follows: MHC α -chains, *red*; MHC β -chains, *green*; antigenic peptides, *black*; zinc atom, *magenta*; TCR V α chain, *yellow*; TCR V β chain, *grey*; SpeC, *blue* with important interface residues highlighted in *orange*.

that is thought to be independent of the ability to activate T cells (261). Although manageable, some of the side effects seen in TTS Phase I and Phase II clinical trials included nausea, vomiting, and diarrhea (323, 338, 342), and may have been related to the emetic properties of SEA (371). A potential advantage of engineering a streptococcal SAg as a TTS is that these toxins naturally lack bona fide emetic activity (262), which may result in fewer side effects. Also, SpeC is very well studied in terms of both structure (272, 285, 365) and function for host receptor engagement (277, 286, 366-368), providing a platform for tailoring activity. Herein, it is hypothesized that SpeC mutagenized within the zinc-dependent, high-affinity MHC II binding domain (SpeC_{D203A}) will have reduced superantigenicity while retaining tumouricidal properties and a SpeC_{D203A}-based TTS fusion protein using an engineered scFv that specifically targets human 5T4 (scFv5T4) can be generated (scFv5T4::SpeC_{D203A}). Finally, it is speculated that in a humanized mouse model of colon cancer, the scFv5T4::SpeC_{D203A} TTS will control the growth potential of an established colon cancer tumour, and that this anti-tumour activity requires both specific targeting by the scFv5T4 moiety, as well as SAg function.

This dissertation is based, in part, on the publication “Control of established colon cancer xenografts using a novel humanized single chain antibody-streptococcal superantigen fusion targeting the 5T4 oncofetal antigen” Patterson KG, Dixon Pittaro JL, Bastedo PS, Hess DA, Haeryfar SMM, McCormick JK (2014) PLoS ONE 9(4): e95200 and has been reformatted to departmental guidelines.

CHAPTER 2: METHODS AND MATERIALS

2.1 Ethics statements

Experiments using primary human lymphocytes were reviewed and approved by Western University's Research Ethics Board (REB) for Health Sciences Research Involving Human Subjects (**Appendix 1**). Informed written consent was obtained from all blood donors were performed under REB 09911E. All animal experiments were performed by Animal Use Protocol (AUP) Number: 2012-026 in accordance with the Canadian Council on Animal Care Guide to the Care and Use of Experimental Animals, and was approved by the Animal Use Subcommittee at Western University (London, ON, Canada) (**Appendix 2**)

2.2 Cell culture growth conditions

2.2.1 Bacterial cell growth conditions

E. coli strains were grown aerobically at 37°C or room temperature (RT) in Difco™ Luria-Bertani (LB) broth with shaking (BD Biosciences, Franklin Lakes, NJ, USA) or on LB with 1.5% Difco™ Agar (BD Biosciences, Franklin Lakes, NJ, USA), and if required, the following antibiotics to maintain target plasmids or endogenous mutations: kanamycin (50 µg mL⁻¹ for BL21 [DE3] and 15 µg mL⁻¹ for Origami B [DE3]), chloramphenicol (10 µg mL⁻¹), ampicillin (100-200 µg mL⁻¹), and/or tetracycline (12.5 µg mL⁻¹) (all from Sigma-Aldrich, St. Louis, MO, USA). For storage, bacterial strains were frozen in LB with 20% glycerol and maintained at -80°C. All bacterial strains used within this study are listed in **Table 9**.

2.2.2 Tissue culture media, growth conditions, and propagation

All tissue culture basal media (Gibco®, Life Technologies Inc, Carlsbad, CA, USA) was supplemented with 10% heat-inactivated fetal bovine serum (FBS; Sigma-Aldrich, St. Louis, MO, USA) and the following supplements, all supplied from Gibco®: 10 mM N-2-hydroxyethylpiperazine-N-2-ethane sulfonic acid (HEPES), 2 mM L-Glutamine, 1 mM sodium pyruvate, 100 µM non-essential amino acids, 100 µg mL⁻¹ streptomycin, and 100 U mL⁻¹ penicillin (Gibco®, Life Technologies Inc, Carlsbad, CA, USA) all filtered through 0.2 µm PES filter (Nalgene™, Thermo Scientific, Waltham, MA, USA).

All cells used within this study and respective complete supplemented medias for each cell line are listed in **Table 10**.

To prepare cultures from cryopreservation, cells were thawed quickly within a 37°C water bath and diluted 1:10 in pre-warmed media with no antibiotics. Cells were pelleted by centrifugation at $330 \times g$ (Allegra 6, Beckman Coulter, Brea, CA, USA) for 5 min at RT, and the supernatant removed. The pellet was gently washed 3× following the same centrifugation, and after the final wash, the cells were seeded onto a 25 cm² or 75 cm² tissue culture flask, dependent on cellular concentration of adherent cells. All tissue culture cells were maintained at 37°C with 5% CO₂ in FBS supplemented complete media. At 70-80% confluence, the cells were harvested for subculturing by removal of the media, and gently rinsing the cells with 1× phosphate buffered saline (PBS) (Gibco®, Life Technologies Inc, Carlsbad, CA, USA). The cells were incubated with cold 0.05% Trypsin-0.53 mM ethylenediaminetetraacetic acid (EDTA) (Gibco®, Life Technologies Inc, Carlsbad, CA, USA) for 5 min at 37°C with 5% CO₂ and gently rocked to detach the cells. Pre-warmed complete culture media with FBS was added immediately to the flask (1:1) to neutralize the trypsin and collect detached cells. The cells were collected by centrifugation at $330 \times g$, for 5 min at RT and resuspended in completed media with FBS and reseeded based on subculture ratio (**Table 10**).

For cryopreservation, cell cultures with no exposure to antibiotics, were harvested as above and prior to reseeded, an aliquot stained with trypan blue exclusion dye (1:1) (Gibco®, Life Technologies Inc, Carlsbad, CA, USA) was counted using a haemocytometer. Cells were pelleted as above and resuspended in cold FBS with 10% dimethyl sulfoxide (DMSO). Cells were quickly transferred to cryopreservation vials and placed at -20°C for 2-3 h (or until frozen) and subsequently stored at -80°C for overnight (O/N) or until relocated to liquid nitrogen vapor cryotank for long-term storage.

The HT-29 cells tested negative for murine pathogens and *Mycoplasma* spp. using Infectious Microbe PCR Amplification Test III (IMPACT III) profiling prior to use in animal models (IDEXX BioResearch Laboratories, Westbrook, ME, USA).

Table 10. Cell lines and primary cells used within the study

PBMCs	<i>Homo sapiens</i> (human); Source: whole blood	cRPMI-1640 + 10% FBS	N/A	Various donors	N/A

Human peripheral blood mononuclear cells (PBMCs) were prepared from the whole blood of healthy donors and isolated by density centrifugation over Ficoll-Paque Plus (GE Healthcare Life Sciences, Piscataway, NJ, USA). In brief, heparinized whole blood was diluted 1:1 with RPMI-1640 (Gibco®, Life Technologies Inc, Carlsbad, CA, USA), layered on top of Ficoll-Paque Plus, and components separated by centrifugation at $910 \times g$ (Allegra 6, Beckman Coulter, Brea, CA, USA) for 1 h, with no applied brake for deceleration. The buffy coat layer containing the PBMCs was collected and washed 2×20 min with RPMI-1640 by centrifugation at $510 \times g$. PBMCs were diluted in cRPMI-1640 with 10% heat-inactivated FBS for experimental use and an aliquot stained with trypan blue exclusion dye (Gibco®, Life Technologies Inc, Carlsbad, CA, USA) was used to quantify cell concentration with a haemocytometer. Reagents and media used for isolation were pre-warmed prior to use. PBMCs were cultured within a tissue culture flask and maintained at 37°C with 5% CO_2 .

2.3 Plasmid isolation

Plasmid DNA was isolated and purified from 1-2 mL of pelleted *E. coli* in stationary phase (O/N aerobic growth at 37°C) with QIAprep Spin Miniprep Kit (Qiagen, Venlo, Limburg, Netherlands) as per manufacturer's protocol. Plasmid DNA was eluted in 10 mM Tris·Cl, pH 8.5 and stored at -20°C . For preparation and concentration of plasmids for transfection, 6-10 mL of pelleted *E. coli* in stationary phase was processed for purification over a single column and eluted in 20-30 μl 10 mM Tris·Cl, pH 8.5. All plasmids generated within this study are listed in **Table 11**.

2.4 DNA visualization and quantification

DNA was visualized on 0.8%, 1%, or 1.2% UltraPure™ Agarose (Invitrogen, Life Technologies Inc, Carlsbad, CA, USA) in $1 \times \text{TAE}$ dependent on desired resolution. Electrophoresis was performed for 1 h at 100 V (Bio-Rad Laboratories Inc, Hercules, CA, USA) of DNA samples, containing loading dye, followed by staining with ethidium bromide (EtBr) solution for visualization under ultraviolet light (Gel Doc™, Bio-Rad Laboratories Inc, Hercules, CA, USA). For size determination, experimental DNA was compared to 1 Kb Plus DNA Ladder (Invitrogen, Life Technologies Inc, Carlsbad, CA,

USA). Buffer and reagent composition is in **Table 12**. All DNA was quantified, using a NanoDrop 1000 Spectrophotometer (Thermo Fisher Scientific Inc, Waltham, MA USA).

2.5 DNA gel extraction

To isolate and purify DNA fragments by gel extraction, digested DNA was separated by gel electrophoresis on 0.6% agarose UltraPure™ Agarose (Invitrogen, Life Technologies Inc, Carlsbad, CA, USA) in 1×TAE for 1 h at 100 V (Bio-Rad Laboratories Inc, Hercules, CA, USA) and stained with EtBr solution. Desired fragments were excised under ultraviolet light and purified using QIAquick Gel Extraction Kit (Qiagen, Venlo, Limburg, Netherlands) as per manufacturer's protocol and eluted in 10 mM Tris·Cl, pH 8.5.

2.6 Ethanol precipitation

Concentration of plasmid DNA for transfection purposes was performed by adding 1/10 volume of cold (4°C) 3 M sodium acetate to the DNA sample followed by 2× volume of cold (-20°C) 95% EtOH. The DNA was incubated at -20°C for 25 min and pelleted by centrifugation at $21\,000 \times g$ for 10 min at 4°C. The pellet was washed by inversion with 0.75 mL cold (-20°C) 70% EtOH and centrifugation repeated for 5 min. EtOH was decanted and remaining evaporated for ~25 min prior to pellet resuspension in a low volume (10-15 µl) of 10 mM Tris·Cl, pH 8.5.

2.7 Primer generation

Primers were designed using the software Primer3Plus Version: 2.3.6 (374) and synthesized by Sigma Life Sciences (St. Louis, MO, USA). Primers were rehydrated as master stocks as 100 µM and diluted 1:10 for working stocks, both in sterile Milli-Q water (Millipore, Bedford, MA, USA). Primers used within the study listed in **Table 13**.

2.8 Polymerase chain reaction

Polymerase chain reaction (PCR) products were amplified (Peltier Thermocycler PTC-200, MJ Research, Waltham, MA, USA) with reactions containing 0.3 mM deoxyribonucleotide triphosphates (dNTPs; Roche Diagnostics, Basel, Switzerland),

Table 12. Buffer composition and reagents used within the study

Reagent	Composition	Application
Coomassie Blue staining solution	45% (v/v) methanol, 10% (v/v) glacial acetic acid, 0.1% (w/v) Coomassie Brilliant Blue R-250	Protein visualization
Destain solution	45% (v/v) methanol, 10% (v/v) glacial acetic acid	Protein visualization
DNA loading dye (6×)	40% (v/v) glycerol, 0.25% (w/v) bromophenol blue	DNA visualization
FACS Buffer	2% FBS, 0.01% sodium azide in 1×PBS	FACS
HEPES Buffer (1×)	150 mM NaCl, 10 mM 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid (HEPES), pH 7.4	Protein purification
Laemmli buffer (4×)	240 mM Tris pH 6.8, 8% (w/v) SDS, 40% (v/v) glycerol, 0.01% (w/v) bromophenol blue, 1% (v/v) β-mercaptoethanol	Protein visualization
PBS (1×)	137 mM NaCl, 10 mM Na ₂ HPO ₄ , 2.7 mM KCl, 1.8 mM KH ₂ PO ₄ , pH 7.4	Various
PBST (1×)	137 mM NaCl, 10 mM Na ₂ HPO ₄ , 2.7 mM KCl, 1.8 mM KH ₂ PO ₄ , 0.1% (v/v) Tween-20	Various
PFU Buffer (1×)	20 mM Tris-HCl (pH 8.8), 10 mM (NH ₄) ₂ SO ₄ , 10 mM KCl, 0.1% (v/v) Triton X-100, 0.1 mg mL ⁻¹ BSA, 2 mM MgSO ₄	Molecular cloning: PCR
Polyacrylamide resolving gel (12%)	12% (v/v) acrylamide/bisacrylamide (37.5:1) aqueous solution, 0.25% (v/v) 1.5 M Tris-HCl pH 8.8, 0.1% (w/v) SDS, 0.1% (w/v) APS, 0.15% (v/v) TEMED	Protein visualization
Polyacrylamide stacking gel (5%)	1.3% SDS, 25% v/v 0.5 M Tris-HCl pH 6.8, 5% v/v acrylamide/bisacrylamide (37.5:1) aqueous solution, 0.1% (w/v) APS, 0.2% (v/v) TEMED	Protein visualization
PSI broth	2% (w/v) tryptone, 0.5% (w/v) yeast extract, 0.5% (w/v) MgSO ₄ , pH 7.6	Chemical competent cells
TAE (1×)	40 mM Tris-acetate, 1 mM EDTA, pH 8.0	DNA visualization
TBS	50 mM Tris-HCl pH 7.6, 150 mM NaCl	Histology
TBST (1×)	50 mM Tris-HCl pH 7.6, 150 mM NaCl, 2.5% Tween-20	Histology
Tfbl solution	100 mM RbCl ₂ , 50 mM MnCl ₂ ·4H ₂ O, 30 mM CH ₃ COOK, 10 mM CaCl ₂ , 15% (v/v) glycerol, pH 5.8	Chemical competent cells

TfbII solution	75 mM CaCl ₂ , 10 mM C ₇ H ₁₅ NO ₄ S (MOPS), 10 mM RbCl ₂ , 15% (v/v) glycerol, pH 6.5	Chemical competent cells
Tris-Glycine Running buffer (1×)	192 mM glycine, 25 mM Tris, 0.1% (w/v) SDS, pH 8.3-8.6	Protein visualization
Western Blot Transfer Buffer	20% methanol, 48 mM Tris base, 39 mM glycine, 0.037% (w/v) SDS	Protein visualization

^a Underlined nucleotides represent restriction enzyme recognition site

5 mM MgSO₄, 1 μM oligonucleotide primers, 1×PFU buffer, 1 μl template DNA and 1:100 *Pfu* polymerase (generated internally, unpublished). Oligonucleotides (Sigma Genosys, St. Louis, MO, USA) are listed in **Table 13**. Amplification was performed with the following standard conditions: initial denature at 95°C for 5 min followed by repeated cycles (36×) of denaturing at 95°C for 1 min, annealing with primer-specific temperature for 30 sec [as designed with Primer3.0 Plus software (374)], and extension at 74°C at 1 kb min⁻¹, with final extension at 74°C for 5 min and maintained at 4°C until further processing. PCR products were purified with QIAquick PCR Purification kit (Qiagen, Venlo, Limburg, Netherlands) as per manufacturer's protocol and eluted in 10 mM Tris·Cl, pH 8.5.

2.9 Sequencing

All plasmid DNA inserts were sequenced at the DNA Sequencing Facility at Robarts Research Institute (Western University, London, ON, Canada) using standard T7 promoter and T7 terminator primers, or specifically designed primers, all listed in **Table 13**. DNA concentrations and primers were prepared as per requirements of the DNA Sequencing Facility.

2.10 Molecular cloning

2.10.1 Restriction digestions

Restriction enzyme digestion of DNA was performed as per manufacturer's specifications (New England BioLabs Inc, Ipswich, MA, USA or Roche Diagnostics, Basel, Switzerland). In brief, for the specific restriction enzymes used within this study, a digestion reaction containing target DNA, 1 U enzyme μg⁻¹ DNA, 1× enzyme-specific buffer and if required, 1× bovine serum albumin (BSA) (New England BioLabs Inc, Ipswich, MA, USA), was incubated for 1-2 h in a 37°C water bath. Double digestion completion was compared to single digestion controls by visualization on a 1% agarose gel as above and subsequently purified with QIAquick PCR Purification kit (Qiagen, Venlo, Limburg, Netherlands) as per manufacturer's protocol with final elution in 10 mM Tris·Cl, pH 8.5.

2.10.2 DNA ligations

Ligations of DNA were performed for 1 h in a water bath at 16°C with reactions containing 40 U T4 DNA Ligase (New England BioLabs Inc, Ipswich, MA, USA), 1× T4 Ligase Buffer (New England BioLabs Inc, Ipswich, MA, USA), and appropriate concentrations of digested vector and insert. A standard reaction had ~100 ng total vector DNA and ~1 µg total insert DNA, calculated from a molar ratio of either 1:1 or 3:1 (insert:vector), based on the size variation of the insert compared to the vector. Blunt-end ligations used a molar ratio of 5:1 (insert:vector).

2.10.3 Competent cell preparation

2.10.3.1 Chemical competent *E. coli* preparation (rubidium chloride; RbCl)

E. coli strains were inoculated 1:100 from stationary phase (O/N growth at 37°C) into PSI broth and grown aerobically at 37°C to optical density (OD)₆₀₀ = 0.5. Cells were incubated on ice for 15 min prior to centrifugation at 2400 × g for 5 min at 4°C (Beckman Avanti® J-25 High Speed Centrifuge, Beckman Coulter, Brea, CA, USA). Cell pellets were gently resuspended and incubated for 15 min on ice in 0.4× original volume of TfbI solution. After repeated centrifugation, cells were resuspended in 0.04× original volume of TfbII solution and incubated 15 min on ice prior to aliquoting and immediate -80°C storage. Buffer and reagent composition are listed in **Table 12**.

2.10.3.2 Chemical competent *E. coli* preparation (calcium chloride; CaCl₂)

E. coli strains were inoculated 1:100 from stationary phase (O/N growth at 37°C) into LB broth and grown aerobically at 37°C to OD₆₀₀ = 0.5. Cells were incubated on ice for 10 min prior to centrifugation at 4000 × g for 5 min at 4°C (Beckman Avanti® J-25 High Speed Centrifuge, Beckman Coulter, Brea, CA, USA). Cell pellets were gently resuspended in 10 mL of cold 0.1 M CaCl₂ and incubated for 20 min on ice. After repeated centrifugation, cells were gently resuspended in 5 mL cold 0.1 M CaCl₂ with 15% (v/v) glycerol and aliquoted for immediate use or -80°C storage.

2.10.3.3 Electrocompetent *E. coli* preparation

Electrocompetent cells were prepared with *E. coli* from stationary phase (O/N growth at 37°C) by subculturing 1:500 into LB media (5 mL) with appropriate antibiotics and grown for 3 h at 37°C, with shaking. The cells were pelleted by centrifugation at $2100 \times g$ for 5 min at 4°C and pellet resuspended in 5 mL ice cold 10% glycerol. Centrifugation was repeated and the pellet was resuspended in 1 mL ice cold 10% glycerol followed by a final centrifugation and resuspension in 0.2 mL ice cold 10% glycerol. Cells were aliquoted into 0.1 mL fractions and immediately used for transformation or placed at -80°C for storage.

2.10.4 Transformation and transfection

2.10.4.1 Chemical competent *E. coli* transformation

To transform chemical competent *E. coli*, the ligation reaction (~10 µL) was added to the cell aliquot once thawed on ice, and incubated for 30 min remaining on ice. The cells were incubated at 42°C for 45 sec (RbCl₂-competent cells) or 2 min (CaCl₂-competent cells) for heat shock and subsequently placed on ice for 2 min. LB culture media (0.9 mL) was added to the cells prior to incubation for 1 h at 37°C with shaking. The transformation was cultured by spread plating (200 µL per plate) on LB Agar with appropriate antibiotics and grown O/N (18-24 h) at 37°C.

2.10.4.2 Electroporation of *E. coli*

Plasmid DNA (1 µL) was added to electrocompetent *E. coli*, prepared as described, and incubated on ice for 3 min. Samples were loaded into 0.2 cm electroporation cuvettes (VWR, Radnor, PA, USA) and pulsed at 200 Ω, 25 µF, 2.5 kV for 5 ms (Gene Pulser Xcell™ System, Bio-Rad Laboratories Inc, Hercules, CA, USA). The cells were immediately resuspended in 1 mL of LB culture media and incubated for 1 h at 37°C with shaking. The transformation was cultured by spread plating dilution series from 10⁻¹-10⁻³ on LB Agar with appropriate antibiotics and grown O/N (18-24 h) at 37°C.

2.10.4.3 Cellular transfections for gene expression

HEK293 cells were seeded as required into multi-well tissue culture plates (Corning Inc, Corning, NY, USA) with cMEM + 10% FBS and allowed to grow O/N (18-24 h) at 37°C with 5% CO₂. Liposome:DNA complexes were formed using Lipofectamine® 2000 (Life Technologies Inc, Carlsbad, CA, USA) and plasmid DNA of choice, as per manufacturer's protocol at a ratio of 2 µl lipofectamine:0.8 µg DNA. In brief, complexes were formed in cMEM without FBS or antibiotics. Transfection of cells occurred in the same media for 4 h at 37°C with 5% CO₂, after which the media was removed and replaced with cMEM + 10% FBS for plasmid expression over 24 h.

2.10.5 *E. coli* clone selection

Clones were screened for successful DNA ligation and transformation by selecting individual colonies that were subsequently grown O/N and plasmid isolation performed. Plasmids were visualized for band shifts on 1% agarose gels as described, as well as the insert size verified by restriction enzyme digestion and DNA sequencing performed for final sequence confirmation. Alternatively, DNA screening was performed by colony PCR. Individual colonies were inoculated into single PCR tubes by a sterile toothpick and the reaction buffer (as described) containing T7 forward and T7 terminator primers added. Amplification was performed with the following standard conditions: initial denaturing at 95°C for 10 min followed by repeated cycles (36×) of denaturing at 95°C for 30 sec, annealing with primer-specific temperature 63°C for 30 sec, extension at 74°C at 1 kb min⁻¹, and maintained at 4°C until further processing. PCR products were visualized by electrophoresis and staining with EtBr as described.

2.11 Generation of protein expression vectors

Using standard molecular cloning techniques, protein expression clones in pET-41a were altered such that the enterokinase (EK) cleavage site (DDDDK↓X), was replaced with a Tobacco Etch Virus (TEV) protease cleavage site (ENLYFQ↓S) (368). To enable biotin labeling of proteins, a protease cleavable C-terminal biotin ligase recognition sequence (biotin tag) (GLNDIFEAQKIEWHE; AviTag™, Avidity LLC, Aurora, CO, USA)

containing a 5' gly-gly spacer was genetically engineered onto genetic constructs within the reverse cloning primers (**Table 13**). All constructs were transformed into both *E. coli* XL1 Blue for plasmid preservation and *E. coli* BL21 (DE3) or Origami B (DE3) for protein expression (**Table 11**).

2.12 Generation of SpeC protein expression clones and variants

Plasmid constructs containing *speC_{WT}* (372), *speC_{Y15A}* (368) and *speC_{D203A}* (286) for expression within pET-41a were previously described. In this study, *speC_{Y15A/D203A}* for protein expression was generated. The 627 bp gene was amplified by standard PCR with an annealing temperature of 55°C from a previously generated construct containing *speC_{Y15A/D203A}* (373) using primers in **Table 13**. The resulting PCR product was cloned into pET-41a::TEV for protein expression using standard molecular cloning techniques as described and transformed into *E. coli* BL21 (DE3).

2.13 Generation of murine scFv5T4 and linked SpeC variants for protein expression

Expression pET-28a constructs containing murine *scFv5T4* alone (372) or genetically linked *speC_{D203A}* or *speC_{Y15A/D203A}* (373) were previously generated. In this study, the linked constructs were developed further to include a C-terminal biotin tag, as described, which was added by standard PCR amplification with an annealing temperature of 50°C. Primers used are listed in Table 13. The resulting 1443 bp product was initially generated within pBluescript II SK (+) as an intermediate step with blunt-end ligation and subsequently by standard cloning techniques, into pET-28a for protein expression. For further product development, the murine scFv5T4 alone was designed to contain a C-terminal biotin tag and codon optimized for expression in *E. coli*. The 798 bp gene was manufactured by GenScript Corp (Piscataway, NJ, USA) and cloned by restriction enzyme digestion and standard techniques into pET-28a as well as pET-32a, an expression vector containing N-terminal thioredoxin (TrxA) and His₆ tags. The synthesized scFv5T4 was genetically linked to previously constructed *speC_{D203A}* or *speC_{Y15A/D203A}* with existing biotin tags by standard cloning methods and transformed into either *E. coli* BL21 (DE3) or Origami B (DE3) for co-expression with pBirAcm.

2.14 Design and generation of humanized scFv5T4 construct for protein expression

The humanized scFv was designed in this study based on the predicted CDRs of the characterized murine scFv specific for the human 5T4 TAA (243). The cDNA sequence for a humanized *scFv5T4* was recoded for *E. coli* expression and manufactured by GenScript Inc (Piscataway, NJ, USA). Amino acid substitutions were made in the backbone sequence of scFv5T4 from the original murine sequence (243), determined by aligning with a human consensus sequence. The consensus sequence was generated from 10 previously sequenced human scFv fragments taken from NCBI Protein Database (www.ncbi.nlm.nih.gov/protein) and aligned using MacVector (MacVector Inc, Cary, NC, USA). The CDR loops specific for 5T4, and the immediate amino acids flanking the predicted loops were not altered to maintain antibody structure and specificity. Amino acids within the CDRs were determined based on predicted topological modeling using PyMol Software (Schrödinger, New York, NY, USA) of scFv5T4 with the structure modeled from human 80R scFv (PDB 2GHW22) (375) with 75.9 sequence identity by SWISS-MODEL (www.swissmodel.expasy.org). Lastly, the gene was also designed to include a TEV cleavable C-terminal biotin tag as well as restriction enzyme sites for strategic cloning purposes. The synthesized 819 bp gene was cloned by restriction enzyme digestion using standard techniques into pET-32a for protein expression. The final construct development was to arrange the protease cleavage sites so that the TEV recognition site was N-terminal for TrxA and His₆ removal and the EK recognition site was C-terminal for removal of the biotin tag. The construct was amplified by PCR, with an annealing temperature of 65°C. The primers used are listed in **Table 13**. The resulting product for scFv5T4 was cloned by standard molecular techniques into pET-32a for protein expression in either *E. coli* BL21 (DE3) or Origami B (DE3) for co-expression with pBirAcm.

2.15 Generation of humanized scFv5T4 linked mRFP1

mRFP1 was amplified by standard PCR with an annealing temperature of 58°C from previously generated shuttle vector pMSP3535::*mRFP1* (**Table 11**). The resulting 687 bp product, containing a GGP linker was translationally fused to humanized *scFv5T4* by

standard molecular cloning procedures within pET-32a vector. The final construct was transformed into *E. coli* BL21 (DE3) for protein expression. Primers are listed within **Table 13**.

2.16 Generation of humanized scFv5T4 linked SpeC variants

Humanized *scFv5T4* from the pUC57::*scFv5T4* construct was genetically linked with previously biotin-tagged *speC_{D203A}* or *speC_{Y15A/D203A}* by restriction enzyme digestion and standard molecular cloning techniques into pET-32a to generate protein expression constructs. The final constructs were amplified by PCR, with an annealing temperature of 65°C to arrange the protease cleavage sites so that the TEV recognition site was N-terminal for TrxA and His₆ removal and the EK recognition site was C-terminal for removal of the biotin tag. Primers used are listed in **Table 13**. The resulting 1443 bp products were cloned into pET-32a and were transformed for co-expression with pBirAcm in *E. coli* BL21 (DE3) or Origami B (DE3).

2.17 Generation of transfection plasmids for human cell lines

Transfection vectors pCMV6-XL5::*5t4* and pEGFP-N1 were purchased from Origene Technologies, Inc. (Rockville, MD, USA), and Clontech Laboratories, Inc. (Mountain View, CA, USA), respectively. pEGFP-N1::*5t4* engineered to genetically link *5t4* to *eGFP* was previously generated (372). In this study, control vehicle pCMV6-XL5 was generated by removal of *5t4* from pCMV6-XL5::*5t4* by restriction enzyme digestion and the remaining fragment purified from gel electrophoresis and ligated to complete the vector. Transfection control vector pCMV6-XL5::*eGFP* was generated by the replacement of *5t4* of pCMV6-XL5::*5t4* with *eGFP* from pEGFP-N1 (replicated in *E. coli* SCS110) by restriction enzyme digestion and standard molecular techniques. The resulting constructs (**Table 11**) were transformed into *E. coli* XL1 Blue.

2.18 Protein visualization

2.18.1 Sodium Dodecyl Sulfate Polyacrylamide Gel Electrophoresis (SDS-PAGE)

To visualize proteins, 1-D vertical gel electrophoresis was performed for 50 min at 200 V

(Mini-PROTEAN System, Bio-Rad Laboratories Inc, Hercules, CA, USA) using 12% polyacrylamide resolving gels with 5% stacking gels in Tris-Glycine Running Buffer. Prior to electrophoresis, samples were mixed 3:1 with 4× Laemmli buffer and boiled for 5 min. Gels were fixed and stained for 1 h with coomassie blue staining solution containing Coomassie Brilliant Blue R-250 (Bio-Rad Laboratories Inc, Hercules, CA, USA) followed by replacing destain solution several times until background of the gel was resolved. For size determination, experimental proteins were compared to Prestained Broad Range P7708S Protein Marker (New England BioLabs Inc, Ipswich, MA, USA). Buffer and reagent composition are listed in **Table 12**.

2.18.2 Western Blot

To probe specific proteins, samples were separated by gel electrophoresis by SDS-PAGE on 12% polyacrylamide resolving gels as described, without end-stage staining. To immobilize proteins for detection, the samples were transferred from the gel matrix to an Immobilon-FL polyvinylidene difluoride (PVDF) membrane (EMD Millipore, Billerica, MA, USA) by electroblotting (Mini Trans-Blot® Cell, Bio-Rad Laboratories Inc, Hercules, CA, USA) for 1 h at 100 V (or 25 V O/N). Prior to transfer, the membrane was immersed for 5 min in methanol (100%) and equilibrated in Western blot transfer buffer. After transfer, to reduce non-specific binding, the membrane was blocked for 0.5 h with 5% (w/v) non-fat dry milk in 1×PBS. For specific protein detection the biotinylated tag was probed for 1 h with conjugated streptavidin-IRDye800 (1:10 000 in 1×PBS with 1% [w/v] non-fat dry milk). The membrane was washed 3× 15 min with 1×PBST prior to viewing with LI-COR Odyssey® Infrared Imaging System (LI-COR, Lincoln, NE, USA). All incubations had slight agitation. Buffer and reagent composition are located in **Table 12**.

2.19 Protein expression and purification

Recombinant proteins were produced using an *E. coli* BL21 (DE3) or Origami B (DE3) expression system. For biotinylation of proteins, the *E. coli* was engineered by bacterial transformation to contain pBirAcm, an IPTG inducible plasmid containing the *birA* gene encoding biotin ligase. Cells were grown aerobically, with shaking, at 37°C in LB

medium with the appropriate antibiotics to $OD_{600} = 0.5$. For the final constructs, protein expression was induced O/N (18-24 h) at RT with 0.2 mM IPTG (Bio Basic Inc, Markham, ON, Canada) and biotinylated with the addition of 50 μ M D-biotin (Bio Basic Inc, Markham, ON, Canada). Cells were pelleted at 4°C, $7000 \times g$ for 5 min and resuspended in cold 20 mM Tris-HCl, pH 7.4, 200 mM NaCl (or 1×HEPES Buffer for SAg alone) containing 0.25 mg mL⁻¹ lysozyme (Sigma-Aldrich, St. Louis, MO, USA) and 0.02 mg mL⁻¹ DNaseI (Sigma-Aldrich, St. Louis, MO, USA). Cells were incubated on ice for 1 h prior to lysis with a continuous head flow cell disruptor (Constant Systems Ltd, Daventry, United Kingdom) at 25 psi, followed by sonication with output 4, using 1 pulse per mL of sample. Cellular debris was pelleted at 4°C, $10\,000 \times g$ for 10 min. Supernatants were applied to a charged (100 mM NiSO₄) Ni-NTA affinity column (Novagen, EMD Millipore, Billerica, MA, USA), washed with buffer and eluted with increasing concentration of imidazole (5 mL each of 15 mM, 30 mM, 60 mM, and 200 mM imidazole in 20 mM Tris-HCl, pH 7.4, 200 mM NaCl or 1×HEPES Buffer). Purified fractions were dialyzed 3× against the respective buffer and the N-terminal tags cleaved by autoinactivation-resistant His₇::TEV (376) as previously described (377) with O/N (18-24 h) incubation at RT. Cleaved proteins were applied and eluted as described from a second Ni-NTA affinity column to remove TEV protease and obtain a pure protein. Proteins were dialyzed 3× against the respective buffer or 0.9% NaCl (saline), assessed for homogeneity and purity by SDS-PAGE, and quantified with Pierce™ BCA Protein Assay Kit (Thermo Fisher Scientific Inc, Waltham, MA, USA) using manufacturer's instructions. In brief, protein aliquots were mixed with the kit formulation, based on bicinchoninic acid (BCA), for colorimetric detection of protein complexes at absorbance 562 nm (Bio-Rad Microplate Reader 680, Bio-Rad Laboratories Inc, Hercules, CA, USA). The protein quantification was reported with reference to a common protein standard, BSA.

2.20 Binding detection of humanized scFv5T4 to 5T4 antigen

HT-29 (1.0×10^6) or transfected HEK293 cells (1.0×10^6) containing either pCMV6-XL5 or pCMV6-XL5::5T4, were incubated for 1 h at RT with either anti-human mAb5T4 (1:200; ab88091, Abcam, Cambridge, United Kingdom) or scFv5T4-biotin (1:100; 2 mg

mL⁻¹), washed with 1×PBS followed by incubation with fluorescein isothiocyanate (FITC) anti-mouse IgG (1:1000; eBioscience, San Diego, CA, USA) or streptavidin-FITC (1:1000; Rockland Immunochemicals Inc, Pottstown, PA, USA), respectively, for 1 h at 4°C. Cells were washed and either assessed with fluorescence-activated cell sorting (FACS) (BD FACSCanto II, BD Biosciences, Franklin Lakes, NJ, USA) or viewed with fluorescence microscopy (Olympus IX71 Inverted Microscope, Olympus Canada Inc, Richmond Hill, ON, Canada). For FACS analysis, mouse IgG2bκ isotype control was also included (1:200, eBioscience, San Diego, CA, USA). Alternatively, transfected HEK293 cells were incubated with anti-human mAb5T4 (1:200, Clone EPR5529; Abcam, Cambridge, United Kingdom) in conjunction with scFv5T4-biotin (1:100; 2 mg mL⁻¹), for 1 h at RT, followed by tetramethylrhodamine (TRITC) anti-rabbit IgG (1:1000; Jackson ImmunoResearch Labs, West Grove, PA, USA) and streptavidin-FITC (1:1000; Rockland Immunochemicals Inc, Pottstown, PA, USA), for 1 h at 4°C, washed and viewed for co-staining by fluorescence microscopy (Olympus IX71 Inverted Microscope, Olympus Canada Inc, Richmond Hill, ON, Canada). Lastly, HEK293 cells, transfected for expression of either pEGFP-N1::5T4 or vehicle pEGFP-N1, were incubated with scFv5T4::mRFP1 (1:100; 2 mg mL⁻¹) for 1 h at RT and subsequently washed and viewed with fluorescence microscopy (Olympus IX71 Inverted Microscope, Olympus Canada Inc, Richmond Hill, ON, Canada). All microscopy images were taken using ImagePro Plus Software (MediaCybernetics, Rockville, MD, USA) and FACS analysis was completed using FlowJo Software (FlowJo, LLC, Ashland, OR, USA). Buffer reagent composition is in **Table 12** and antibodies and dyes are in **Table 14**.

2.21 SpeC-mediated PBMC proliferation

2.21.1 Radioactive proliferation assay

Human PBMCs were isolated and prepared as described. PBMCs (2×10^5) were cultured in cRPMI + 10% FBS containing 2 $\mu\text{g mL}^{-1}$ Polymyxin B (MP Biomedicals, Santa Ana, CA, USA) with titrating SpeC variants (10^{-4} - 10^0 $\mu\text{g mL}^{-1}$), including SpeC_{WT}, SpeC_{Y15A/D203A}, SpeC_{D203A}, or titrating SpeC variants in addition to scFv5T4, scFv5T4::SpeC_{Y15A/D203A} or scFv5T4::SpeC_{D203A} (2×10^{-2} - 2×10^2 nM) in U-bottom

Table 14. Antibodies and dyes used within the study

Antibody or Dye	Clone or Catalog No.	Dilution	Application	Source
7-AAD	A1310	2 µl	FACS	Molecular Probes, Life Technologies
Alexa Fluor® 488 goat anti-rabbit IgG (H+L)	A-11008	1:400-1:1000	IHC	Life Technologies
AlexaFluor700 anti-human CD8	RPA-T8	1:200	FACS	BD Pharmingen
APC anti-human CD3	UCHT1	1:200	FACS	BD Pharmingen
CFSE	C34554	10 µM	FACS	Molecular Probes, Life Technologies
DAPI nuclear stain	B2261	1:1000	IHC	Sigma-Aldrich
FITC rat anti-mouse IgG	11-4011-85	1:1000	FACS/microscopy	eBioscience
mouse anti-human 5T4	ab88091	1:200	FACS/microscopy	Abcam
mouse IgG2bk Isotype Control	eBMG2b/14-4732-85	1:200	FACS	eBioscience
PE anti-human CD4	RPA-T4	1:200	FACS	BD Pharmingen
rabbit anti-CD3	SP7	1:50	IHC	Abcam
rabbit anti-human 5T4	EPR5529	1:200	FACS/microscopy	Abcam
rabbit anti-Ki67	NB500-170	1:20	IHC	Novus Biologicals
rabbit anti-vWF	A0082	1:400	IHC	Dako
Rhodamine (TRITC) goat anti-rabbit IgG (H+L)	111-025-003	1:1000	FACS/microscopy	Jackson ImmunoResearch Labs
streptavidin-FITC	S000-02	1:1000	FACS/microscopy	Rockland Immunochemicals
streptavidin-IRDye800	S000-32	1:10 000	Western Blot	Rockland Immunochemicals
TACS® 2 TdT In situ FITC Apoptosis Detection Kit	4812-30-K	As per kit	IHC	Trevigen

96-well microplates (BD Biosciences, Franklin Lakes, NJ, USA). Cells were incubated for 72 h and subsequently labeled with ^3H -thymidine (PerkinElmer, Waltham, MA, USA) incorporation for 18 h at 37°C with 5% CO_2 . Cells were harvested to glass-fiber filters and DNA-incorporated ^3H -thymidine was measured in a beta scintillation counter (Wallac 1450 MicroBeta Counter, PerkinElmer, Wallac Oy, Turku, Finland).

2.21.2 CFSE proliferation assay

Human PBMCs were isolated and prepared as described and labeled with CellTrace™ carboxyfluorescein succinimidyl ester (CFSE) Cell Proliferation Kit (carboxyfluorescein diacetate; Molecular Probes®, Life Technologies Inc, Carlsbad, CA, USA) as per manufacturer's instructions. In brief, cells ($10 \times 10^6 \text{ mL}^{-1}$) were suspended in pre-warmed RPMI-1640 and labeled with $10 \mu\text{M}$ CFSE for 10 min in a 37°C water bath, protected from light. To stop the reaction, cold cRPMI + 10% FBS was added to the cells and incubated on ice for 5 min. Cells were pelleted and resuspended for assay. Cells (0.8×10^6 - 1.0×10^6) were cultured in cRPMI + 10% FBS containing $2 \mu\text{g mL}^{-1}$ Polymyxin B (MP Biomedicals, Santa Ana, CA, USA) and treated with either SpeC_{WT} or variants SpeC_{Y15A}, SpeC_{D203A} or SpeC_{Y15A/D203A} ($1 \mu\text{g mL}^{-1}$) and incubated for 5 days at 37°C with 5% CO_2 in 5 mL round-bottom polystyrene tubes (BD Falcon™, BD Biosciences, Franklin Lakes, NJ, USA). Cells were then washed with FACS buffer by centrifugation and stained in the dark with anti-human CD3 (1:200), anti-human CD4 (1:200) and anti-human CD8 (1:200) antibodies for 30 min on ice. Cells were washed in FACS buffer, labeling with 7-aminoactinomycin D (7-AAD; $2 \mu\text{L sample}^{-1}$) and analyzed by FACS (BD FACSCanto II, BD Biosciences, Franklin Lakes, NJ, USA). FACS analysis was completed using FlowJo Software (FlowJo, LLC, Ashland, OR, USA). Buffer and reagent composition are listed in **Table 12** and antibodies and dyes are listed in **Table 14**.

2.22 SpeC-mediated PBMC cytotoxicity assays

2.22.1 JAM-assay

Cytotoxicity *in vitro* was evaluated using the just another method (JAM)-assay (378) by labeling WiDr cells (2.5×10^4) grown O/N (18-24 h) with ^3H -thymidine (PerkinElmer,

Waltham, MA, USA) for 18 h in flat bottom 96-well microplates (BD Biosciences, Franklin Lakes, NJ, USA) at 37°C with 5% CO₂ and incubating with isolated human PBMCs (as described) at an effector:target cell ratio of 10:1 with titrating SAGs (10⁰-10³ ng mL⁻¹) including SpeC_{WT}, SpeC_{Y15A}, and SpeC_{D203A}. Incubation periods in cRPMI + 10% FBS containing 2 µg mL⁻¹ Polymyxin B (MP Biomedicals, Santa Ana, CA, USA) were 24, 48, 72, 96 and 168 h to determine time-response. At each time point, supernatants were aspirated, removing PBMCs and any non-adherent (dead) WiDr cells. Remaining live cells were washed with 1×PBS and incubated with 0.05% trypsin-EDTA (Gibco®, Life Technologies Inc, Carlsbad, CA, USA) for 20 min at 37°C with 5% CO₂ and subsequently harvested to glass-fiber filters. Live cells containing DNA-incorporated ³H-thymidine were measured in a beta scintillation counter (Wallac 1450 MicroBeta Counter, PerkinElmer, Wallac Oy, Turku, Finland). The specific apoptosis was calculated according to the formula with counts per minute (CPM) (spontaneous) condition equivalent to WiDr incubated with PBMCs alone:

$$\% \text{ specific apoptosis} = \frac{\text{CPM}(\text{spontaneous}) - \text{CPM}(\text{experimental})}{\text{CPM}(\text{spontaneous})} \times 100\%$$

2.22.2 Flow cytometry

Human PBMCs were co-cultured with either WiDr or HT-29 cells previously grown (24-48 h) on flat well microplates (BD Biosciences, Franklin Lakes, NJ, USA) at a ratio of 10:1 and titrated SpeC variants for 48 h at 37°C with 5% CO₂ in cRPMI + 10% FBS containing 2 µg mL⁻¹ Polymyxin B (MP Biomedicals, Santa Ana, CA, USA). Cells were harvested and labeled with 7-AAD following the manufacturer's protocol and analyzed by FACS (BD FACSCanto II, BD Biosciences, Franklin Lakes, NJ, USA). Using FlowJo software, the WiDr or HT-29 populations were gated upon by comparison of human PBMC alone samples and subsequently assessed for presence or absence of 7-AAD. Additional experimentation was repeated as above to further include the cytotoxic potential of scFv5T4::SpeC_{D203A}, and controls scFv5T4 and scFv5T4::SpeC_{Y15A/D203A}.

2.22.3 ⁵¹Cr-release assay

Human PBMCs were treated with SAG, scFv5T4, or fusion proteins as in the FACS assay

for 48 h in U-bottom 96-well microplates (BD Biosciences, Franklin Lakes, NJ, USA) at 37°C with 5% CO₂ in cRPMI + 10% FBS containing 2 µg mL⁻¹ Polymyxin B (MP Biomedicals, Santa Ana, CA, USA). Target HT-29 cells were labeled with (Na)₂⁵¹CrO₄ (PerkinElmer, Waltham, MA, USA) in cRPMI + 10% FBS. PBMCs were added at effector:target cell ratios of either 1:1, 5:1 or 10:1 against HT-29. Cytotoxicity was determined after 4–6 h incubation at 37°C with 5% CO₂ in a standard chromium release assay measuring the ⁵¹Cr content of culture supernatants using a gamma-counter (Wallac Wizard 1470 Automatic Counter, PerkinElmer, Wallac Oy, Turku, Finland). Total release control was obtained by exposing target cells to 1% SDS (EMD Millipore, Billerica, MA, USA). The specific lysis was calculated according to the formula:

$$\% \text{ specific lysis} = \frac{\text{experimental release} - \text{spontaneous release}}{\text{total release} - \text{spontaneous release}} \times 100\%$$

2.23 Mouse housing and breeding

Immunodeficient NOD.Cg-*Prkdc*^{scid} *Il2rgt*^{m1Wjl}/SzJ (NSG) mice were bred and housed in an animal barrier facility (Western University, London, ON, Canada) under sterile conditions with food and water ad libitum.

2.24 TTS *in vivo* tumour-killing model

Twenty-eight NSG mice, male and female, aged 13 weeks were used throughout the experimental timeline. Based on a previously developed protocol (242, 335) mice were injected intraperitoneally (ip) with 3×10⁶ HT-29 cells in 0.2 mL vehicle (1×PBS). Three weeks later, once tumours were palpable, the mice were injected ip with either vehicle alone (n=3) or 1×10⁶ human PBMCs in 0.2 mL vehicle (1×PBS). Two hours after receiving PBMCs, 2 µM kg⁻¹ of treatment, controls, or vehicle alone was injected intravenously (iv). Mice were grouped (n=4), ensuring weight- and sex-match distribution (**Appendix 6**), with a random number generator to receive either scFv5T4::SpeC_{D203A}, SpeC_{D203A}, scFv5T4, scFv5T4::SpeC_{Y15A/D203A}, or vehicle alone (saline), however ensuring an even distribution of male and female animals. Mice with no PBMCs received vehicle alone. Intravenous (iv) injections were given daily for 7 additional days. Animals

were monitored and weighed every second day until Day 25 of the experiment (injection of PBMCs), and then daily until end of experiment (Day 60). Primary tumours were measured daily by caliper (height and width) beginning on Day 28 (treatment Day 4) until end of experiment (Day 60). Blood was collected prior to treatment and subsequently drawn once per week after treatment through the saphenous vein. In brief, the animal fur was removed surrounding the vein and Vaseline applied prior to venous puncture, and subsequently collecting drops of whole blood (200 μ L total) in a microfuge tube. Blood was processed by centrifugation for 5 min at $3000 \times g$ and supernatant collected for serum and stored at -20°C . Four weeks after the final injection, the mice were electively euthanized under anesthetics by exsanguination through cardiac puncture for a terminal blood draw and serum was processed as above. The mice were examined visually for overall tumour burden and macro-metastases were scored accordingly based on the degree of regional spread distant from the primary tumour site. All tumours were excised, size- and weight-measured in a blinded fashion and the total tumour volume was calculated. Tumour-associated organs, along with all livers and spleens were also harvested and all tissues were processed for histological assessment as described. All reagents used are listed in **Table 12**.

2.25 Histology of *in vivo* TTS animal model

2.25.1 Histological tissue processing, embedding, and sectioning

Tissues were fixed in 10% neutralized formalin buffer (BDH, VWR, Radnor, PA, USA) for 48 h at RT, followed by 5 \times washes with 1 \times PBS every 12 h with a final wash in 70% ethanol. Tissues were dissected as follows: the primary tumours were dissected longitudinally, dividing the tumour in half, and embedded so that the internal surface was exposed for sectioning. The remaining tumours were dissected on an individual basis, with aim to section both tumour with surrounding normal tissue. Livers were dissected into respective lobes: median, right, left, and caudal, and embedded as separate tissues. Spleens were dissected longitudinally and embedded so that the internal surface was exposed for sectioning. Dissected tissues were placed in Fisherbrand™ TRUFLOW™ Tissue and Biopsy Cassettes (Fisher Scientific, Whitby, ON, Canada), processed using

the ‘brain and bone’ program for paraffin wax treatment in a Leica ASP300 (Leica Biosystems, Nussloch, Germany) at the Molecular Pathology Core Facility (Robarts Research Institute, Western University, London, ON, Canada) and were embedded with proper orientation in paraffin wax. Serial sections (5 μ m) of the tissues were cut using MB35 Premier Blades (Thermo Scientific, Waltham, MA, USA) on a Leitz 1512 microtome (Leica Biosystems, Nussloch, Germany) and mounted on Fisherbrand™ Superfrost™ Plus microscope slides (Fisher Scientific, Whitby, ON, Canada). Slides were incubated at 37°C for 48 h and either stored or processed for histological staining. All reagents used are listed in **Table 12**.

2.25.2 Histological staining and immunohistochemistry

Prior to staining or immunohistochemistry (IHC) analysis, sections were deparaffinized and rehydrated using a Leica AutoStainer XL (Leica Biosystems, Concord, ON, Canada) at the Molecular Pathology Core Facility (Robarts Research Institute, Western University, London, ON, Canada). Sections were stained with hematoxylin and eosin (H&E) using a standard protocol within the Leica Autostainer XL (Leica Biosystems, Concord, ON, Canada) and sealed with a coverslip using low-viscosity Richard-Allan Scientific® Cytoseal™ 60 mounting medium (Thermo Scientific, Waltham, MA, USA). For apoptosis detection and IHC staining, all sections of the primary tumours from the TTS treatment group (scFv5T4::SpeC_{D203A}) and control group (scFv5T4::SpeC_{Y15A/D203A}) were used. Specifically, for apoptosis detection, sections were stained with TACS® 2 TdT *in situ* Fluorescein Apoptosis Detection Kit (Trevigen, Gaithersburg, MD, USA) as per the manufacturer’s protocol. In brief, slides were washed for 2× 10 min in 1×PBS, followed by a 30 min incubation in Cytonin™ permeabilization buffer and a 2× 2 min wash in deionized water. Sections were incubated with 1× terminal deoxynucleotidyl transferase (TdT) labeling buffer for 5 min prior to addition of labeling reaction consisting of TdT dNTP mix, cations (Mg²⁺, Mn²⁺, or Co²⁺), TdT enzyme (TACS-Nuclease™) and TdT labeling buffer, incubated for 60 min at 37°C in a humidified chamber. The reaction was stopped by addition of 1×TdT stop buffer for 5 min. Slides were washed 2× 2 min in PBS followed by 20 min incubation in the dark with Strep-Fluorescein solution. Final washes were 3× 2 min in 1×PBS and slides were mounted with VECTASHIELD® Mounting

Medium with 4',6-diamidino-2-phenylindole (DAPI) (Vector Laboratories, Burlingame, CA, USA) and sealed with a coverslip. Reagent composition is listed in **Table 12**.

Prior to IHC staining, sections were pretreated with Target Retrieval Solution (Dako Canada Inc, Burlington, ON, Canada) for 30 min in pre-warmed solution at 95°C within a water bath. Slides were allowed to cool within the solution for 20 min prior to rinsing 3× with RT TBST buffer. Sections were blocked for 30 min at RT with 10% goat serum in TBST. The following primary antibodies were then incubated for 2 h at RT or O/N (18-20 h) at 4°C on separate sections and slides including, anti-Ki67 (1:20; NB500-170, Novus Biologicals, Littleton, CO, USA), anti-vWF (1:400; A0082 Dako Canada Inc, Burlington, ON, Canada) or anti-CD3 (1:50; Clone SP7, ab16669, Abcam, Cambridge, United Kingdom) in tris-buffered saline (TBS) with 1% goat serum. Each slide had at least one negative control where the primary antibody was omitted and instead incubated with TBS with 1% goat serum. Sections were washed 3× with TBST for 10 min followed by incubation with secondary antibody, Alexa Fluor® 488 goat anti-rabbit IgG (1:1000 in TBST with 1% goat serum; Molecular Probes® Life Technologies Inc, Carlsbad, CA, USA) for 1 h at RT with further washing 3× with TBST for 10 min. Sections were counterstained with DAPI nuclear stain (1:1000, Sigma-Aldrich, St. Louis, MO, USA) in TBST for 5 min at RT. Sections were washed prior to application of anti-fade fluorescence mounting medium (Dako Canada Inc, Burlington, ON, Canada) and sealed with a coverslip. Buffer composition is listed in **Table 12** and antibodies are summarized in **Table 14**.

2.25.3 Histological imaging and evaluation

H&E sections were imaged with an Aperio ScanScope™ (Leica Biosystems, Concord, ON, Canada) for full slide scanning and images taken with Aperio ImageScope Viewing Software (Leica Biosystems, Concord, ON, Canada). Images taken for quantification purposes were captured by random field of view selection in a blinded fashion of one serial section at 400× using an Olympus BX61 fluorescent microscope (Olympus Canada Inc, Richmond Hill, ON, Canada) and analyzed by Image-Pro Plus Software (MediaCybernetics, Rockville, MD, USA). Images for figure representative purposes

were taken using a Zeiss Axio Imager Z1 (Carl Zeiss Canada Ltd, Toronto, ON, Canada) and imaged using Zen 2012 Software (Carl Zeiss Canada Ltd, Toronto, ON, Canada). All images were taken in same field of view with the same exposure time for each fluorescence filter.

IHC and apoptosis stains were quantified in a blinded-fashion by manually counting the positive fluorescence signals on each of the captured 5 high-power field of view images (400×) from each animal per treatment group (n=20) and subsequently averaged or index calculated. More specifically, von Willebrand factor (vWF)⁺ blood vessels were considered to be a single, countable microvessel when any endothelial cell or cell cluster demonstrated antibody staining and was clearly separated from an adjacent cluster. For the CD3 stain, any cell showing antibody staining was considered to be a single, countable CD3⁺ cell. For Ki67 and TUNEL, the number of positively stained cells, in addition to the number of DAPI positive cells, per same fields of view, were counted. Indexes (proliferative index and apoptotic score) were defined by dividing the positive stain count by the total number of nuclei in one image and indexes were subsequently averaged from each animal.

2.26 Statistical analysis

Statistical comparisons were performed using an unpaired Student *t* test or by 2-way ANOVA with Bonferroni multiple comparison test (GraphPad Prism Software, La Jolla, CA, USA). Differences were considered significant when $p < 0.05$.

CHAPTER 3: RESULTS

3.1 SpeC mutant generation, expression, and protein purification

Prior work indicated that Tyr¹⁵ was a critical residue for the SpeC SAg to engage the TCR (368), and Asp²⁰³ was necessary to coordinate a zinc-mediated high-affinity interface with the β -chain of MHC II (**Figure 6B**) (272, 286, 369). Indeed, the single Asp²⁰³ to Ala mutation in SpeC has been demonstrated to dramatically reduce toxicity in a lethal model of toxic shock syndrome (369).

To supplement the previously generated variants, a double mutant version of SpeC containing both alanine substitutions at Tyr¹⁵ and Asp²⁰³ was generated to create a SpeC variant that maintained overall protein structure but was anticipated to be non-functional in eliciting an immune response. *speC_{Y15A/D203A}* was amplified by PCR from a previously generated construct containing *speC_{Y15A/D203A}* (373) where the forward primer used to amplify *speC* lacked the coding region for the 27-amino acid signal peptide (362). The resulting PCR product was cloned into pET-41a::TEV to generate a N-terminal translational fusion with glutathione S-transferase (GST) and His₆ purification tags, cleavable by TEV protease. The resulting genetic product, pET-41a::TEV::*speC_{Y15A/D203A}* followed suit with the other translational genetic constructs (**Figure 7A**) for SpeC protein expression.

To generate and purify SAg proteins, following induced bacterial expression of either wild-type SpeC (SpeC_{WT}), SpeC_{Y15A}, SpeC_{D203A}, or SpeC_{Y15A/D203A}, the cell lysate was applied to a nickel resin column and eluted with increasing concentration of imidazole with the desired protein verified at the anticipated molecular weight of 59 kDa (**Figure 7B**). The purification tags were removed with autoinactivation-resistant His₇::TEV as described (368) (**Figure 7C**) and purified SpeC was eluted in low imidazole concentrations. Protein containing fractions were confirmed with the expected 25 kDa size (**Figure 7D**) and after buffer exchange, resulted in purified SpeC protein (**Figure 7E**).

Figure 7. Overview of recombinant SpeC SAg protein expression and purification

A) Schematic representation of a *speC* genetic construct contained within pET-41a for SAg protein expression, including TEV protease cleavable N-terminal purification tags, GST and His₆. Representative protein electrophoresis of typical SpeC purification steps including **B)** separation from crude extract (flow) using Ni²⁺-affinity gravity chromatography and elution by increasing imidazole concentrations (mM), **C)** tag removal with autoinactivation-resistant His₇::TEV cleavage (368), **D)** separation from TEV protease with Ni²⁺-affinity gravity chromatography and **E)** final purified SpeC protein. Representative images of coomassie blue stained protein gel electrophoresis of the purification of SpeC_{Y15A/D203A}.

3.2 SpeC-mediated T cell activation and cytotoxicity evaluation

3.2.1 PBMC proliferation and T cell activation

The ability of SpeC_{WT}, SpeC_{Y15A}, SpeC_{D203A}, and SpeC_{Y15A/D203A} to activate human PBMCs was evaluated. Firstly, activation of human PBMCs was assessed by induction of proliferation by incubation with increasing concentration of SAg. Both SpeC_{Y15A} and SpeC_{D203A} were impaired for the ability to expand PBMCs by >100-fold compared with SpeC_{WT}, and the SpeC_{Y15A/D203A} double mutant was unable to induce PBMC proliferation (**Figure 8A**).

Also evaluated was the ability of the recombinant proteins (at 1 µg mL⁻¹) to specifically induce proliferation by measuring generations of dividing cells of human CD3⁺CD4⁺ and CD3⁺CD8⁺ T cell populations using FACS. Based on the dilution of CFSE (CFSE^{low}), SpeC_{WT} and each of the single mutants were able to induce proliferation of both T cell subsets, as shown by the increase percent of CFSE^{low}, while the double mutant failed to induce proliferation of either subset (**Figure 8B**). The total CD3⁺ CFSE^{low} population was 21.7% after incubation with SpeC_{WT}, 16.0% and 18.9% with SpeC_{Y15A} and SpeC_{D203A} respectively, and 1.0% with SpeC_{Y15A/D203A}, comparable to the unstimulated treatment group, with 1.4% CFSE^{low} staining (**Figure 8C**).

3.2.2 PBMC-induced cytotoxicity

The ability of SpeC_{WT} and mutant variants to mediate a cytotoxic PBMC-dependent killing response towards human colon cancer cell line, WiDr, was evaluated *in vitro* by two methods. Firstly, WiDr cells, radiolabeled with ³H-thymidine, were incubated over a 7-day period with human PBMCs and increasing concentrations of SpeC variants WT, Y15A, or D203A. The degree of cytotoxicity against WiDr was measured with a standard JAM-assay (378). Based on DNA fragmentation that occurs as one of the hallmarks of apoptosis, in the JAM-assay first reported by Matzinger (378), the intact DNA of viable cells are trapped within the glass fiber filters during cell harvesting, while the DNA of apoptotic cells as fragments are easily washed through the filter. Therefore, detectable radioactivity reflects the amount of intact DNA and remaining viable cells and is

Figure 8. SpeC-mediated T cell activation

A) Proliferation of human PBMCs mediated by SpeC_{WT} or proteins containing mutated residues Y15A (TCR-binding mutant), D203A (MHC II-binding mutant) or Y15A/D203A was determined by the uptake of ³H-thymidine after 72 h post-stimulation (n=4 in triplicate; data representative of one individual). **B-C)** Proliferation of CFSE labeled-human PBMCs mediated by SpeC_{WT} or proteins containing mutated residues was determined by FACS five days post-stimulation, specifically measuring total CD3⁺ T cell population, CD3⁺CD4⁺ T cells and, CD3⁺CD8⁺ T cells. Data shown (mean ± SEM) is from four independent human donors (n=4; FACS data representative of one individual).

correlated to the degree of cellular death (percent apoptosis) (378, 379). Cellular death was demonstrated in both a time- and dose-dependent manner (**Figure 9A**). After 24 h incubation, there was an evident dose-dependent increase in percent apoptosis with treatment of SpeC_{WT}, however not with either of the mutant variants. The cytotoxic effect mediated by SpeC_{WT} was more profound after 48 h and could also begin to be noted with the higher concentrations of SpeC_{Y15A} and SpeC_{D203A}, although the cytotoxic response appeared dampened considerably compared to SpeC_{WT}. This trend was evident throughout the experimental time course and even 168 h (7 days) post-incubation, mutant versions were revealed to display hindered PBMC cytotoxic effects towards WiDr cells, with the exception at the highest used concentration. Based on the JAM-assay results, subsequent killing assays were performed with a 48 h period of PBMC stimulation.

Secondly, to assess the degree of cytotoxicity further, WiDr cancer cells were co-cultured with human PBMCs and increasing concentration of either SpeC variants WT, Y15A, D203A, or Y15A/D203A and analyzed by FACS (**Figure 9B**). After 48 h incubation, all cells were harvested and stained with 7-AAD, a dye that intercalates with DNA to form a fluorescent complex, however is generally excluded from the intact membrane of live cells in order to measure cell death. Within the WiDr cell population, SpeC_{Y15A} caused a significant reduction in WiDr cytotoxicity compared with SpeC_{WT}, and both the SpeC_{D203A} and SpeC_{Y15A/D203A} mutants failed to induce WiDr cytotoxicity (**Figure 9B**).

These data, including proliferation and cytotoxicity, indicated that TCR and MHC II engagement are important for induction of immune cell-mediated killing by SpeC_{WT}, and that SpeC_{D203A} may be a suitable mutant to reduce or prevent systemic immune cell activation while maintaining full engagement with the TCR.

3.3 Development of genetic constructs and expression of murine scFv5T4 proteins

In order to develop a specific targeting mechanism for SpeC_{D203A}, a single chain variable fragment (scFv) from the characterized mouse scFv (729 bp) specific for the human 5T4 TAA (243) was generated (scFv5T4) (372). This construct, as well as the genetically

Figure 9. Cytotoxicity potential of human PBMC mediated by SpeC_{WT} and SpeC mutants

A) Dose- and time-dependent manner of cytotoxicity directed against human colon cancer cell line (WiDr) elicited by SpeC_{WT} (black), SpeC_{Y15A} (white), and SpeC_{D203A} (grey). Incorporation of ³H-thymidine was used to assess the specific apoptosis (%) of cancer cells in JAM-assay. Data representative of one human PBMC donor. **B)** Dose-dependent cytotoxicity of 7-AAD⁺ WiDr cells measured by FACS after 48 h incubation with human PBMCs and either SpeC_{WT}, SpeC_{Y15A}, SpeC_{D203A}, or SpeC_{Y15A/D203A} (n=3–6 per group represented as mean ± SEM. *p<0.05, **p<0.01, ***p<0.001, compared to SpeC_{WT}).

linked (gly-gly-pro) *speC_{D203A}* or *speC_{Y15A/D203A}*, was cloned into pET-41a and pET-28a (373) (**Figure 10A**). However, these proteins proved difficult for successful protein production within the *E. coli* BL21 (DE3) system. In this study, attempts were taken to improve on the overall protein yield. This involved the optimization of induction time and temperature throughout expression, concentration of the inducer (IPTG), and enhancements on the subsequent purification steps, including the analysis of a variety of diverse buffer compositions to increase solubility. Despite these efforts, the overall expression of soluble proteins containing scFv5T4 resulted in poor production with low protein yield. Efforts to increase purification yield from the soluble fraction, including use of various columns with high performance liquid chromatography (HPLC), although robust, did not result in an improved yield of protein product (data not shown).

To enhance the sensitivity and protein capture within the purification methods, the high affinity and specific interaction between biotin and (strept)avidin molecules was applied to the development of the construct. This peptide tag system has been well established and is commonly developed for the basis of molecular biology products for detection and purification of proteins (380-383). As such, this technology was applied to the pET-28a system with aims to increase protein yield by use of this strong interaction as a purification tag, as well as to develop a more rigorous protein detection method. For the *in vivo* enzymatic biotinylation of the protein, the genetic constructs were designed to include a unique 15 amino acid peptide sequence (AviTag™ Technology, Avidity) that is specifically recognized by the BirA enzyme for the addition of biotin onto the specified peptide sequence (biotin tag). For the addition of the biotin tag to existing genetic constructs, a reverse primer containing the specific sequence along with a TEV protease cleavage sequence site was used. The resulting PCR product was cloned intermediately into pBluescript II SK+ and subsequently into pET-28a, creating a TEV protease cleavable C-terminal translational fusion of the biotinylation peptide tag with *scFv5t4* genetically linked *speC* variants. Similar to the previous translational protein expression plasmids, the resulting constructs were pET-28a::*scFv5t4*::*speC_{Y15A/D203A}*::TEV::biotin, and pET-28a::*scFv5t4*::*speC_{D203A}*::TEV::biotin (**Figure 10B; Table 11**). The *E. coli* BL21 (DE3) clones were further engineered to co-express pBirA, an IPTG inducible plasmid

Figure 10. Genetic construct development for expression of soluble recombinant fusion protein

Codon-optimized version of murine scFv5T4 (grey bar) cloned within **C**) pET-28a construct containing the C-terminal biotin tag and **D**) pET-32a expression vector for addition of N-terminal EK cleavable TrxA and 6×His tag.

containing the BirA gene for protein biotinylation. Upon protein induction, similar to the original design, these constructs did not result in sufficient expression of soluble protein, however the *in vivo* biotinylation of the protein proved successful and aided in the detection sensitivity of the expressed constructs (data not shown). Conversely however, the attempted purification methods utilizing the biotinylated tag were not advantageous to the overall yield of the protein. From these results and after pellet solubilization in 8 M urea, it was determined with that upon targeted gene overexpression in *E. coli*, the proteins formed intracellular, insoluble protein within aggregates, termed inclusion bodies. While the particular optimization completed within this study for inclusion body isolation, purification, protein denaturation, and refolding proved successful from previous constructs mentioned, the concentration yield was low and the success rate for obtaining its native structure was particularly difficult to determine for regaining full biological activity. This method was overall inefficient to obtain adequate protein for proper therapeutic assessment.

For further development of the immunotherapeutic, it was perceived that occasionally in the recombinant protein *E. coli* expression system, low levels of soluble protein expression can occur, despite the use of strong transcriptional and translational signals. It has been noted that this may be due to the mRNA codon usage of the heterologous protein (384-386). Each organism has a preference for codons that are recognized (major codons) whereas those not preferentially used (rare codons) and forced high-level expression of proteins can deplete the pool of rare tRNAs. As a result, this can stall translation, decrease mRNA stability, and can potentially inhibit protein synthesis by generating genetic frame-shifts, deletions, misincorporations, and premature termination of transcription or translation. Within the murine sequence of scFv5T4, 16 rare codons of *E. coli* were noted (7%) (386). The scFv5T4 containing constructs were co-expressed with the genes encoding for a number of the rare codon tRNAs within BL21 (DE3) CodonPlus-RIL cells (Stratagene, La Jolla, California, USA) reducing the number of rare codons to 11 (5%), however no difference in protein expression level was noted (data not shown). Furthermore, the murine *scFv5t4* gene sequence was codon optimized for *E. coli* and synthesized, and subsequently cloned within the pET-28a system (**Figure 10C**;

Table 11). However, the expression of soluble protein remained low from the codon optimized *scFv5t4* gene (data not shown).

Efforts were subsequently focused on increasing protein solubility, with results monitored through protein biotinylation. Firstly, a common approach to address solubility issues is to fuse the target protein with a highly soluble carrier protein (380). TrxA has been widely used as such (380, 387-389), including scFv constructs (390, 391). Secondly, to encourage maintenance of overall protein structure for solubility, the disulfide bridges contained within scFv5T4 require a proper folding environment. To generate a construct conducive to these considerations, the codon optimized *scFv5t4* and genetically linked *speC* constructs were cloned into the pET-32a, a protein expression vector containing EK cleavable N-terminal TrxA and His₆ tags, and transformed into both *E. coli* BL21 (DE3) as well as *E. coli* Origami B (DE3), an *E. coli* designed to improve disulfide bond-dependent protein folding. The resulting genetic products were pET-32a::*scFv5t4*::TEV::biotin, pET-32a::*scFv5t4*::*speC*_{Y15A/D203A}::TEV::biotin, and pET-32a::*scFv5t4*::*speC*_{D203A}::TEV::biotin (**Figure 10D; Table 11**). The *E. coli* was also engineered to contain pBirAcm for *in vivo* biotinylation of each protein construct. All experimental attempts to optimize and increase soluble protein yield, such as those previously mentioned, were assessed. Through all of the efforts, it was clear that sufficient protein yield of the murine scFv5T4, as a soluble product, continued and still remains a challenge within this field.

3.4 Development and generation of humanized 5T4-targeting scFv

In this work, the generated murine scFv5T4 constructs proved to be a challenge for purification, therefore, with aims to advance the specific targeting mechanism for SpeC_{D203A}, a humanized scFv specifically targeted for human 5T4 was designed and generated. This construct should be beneficial as a therapeutic with a reduction in the overall HAMA immunological response. Based on the amino acid sequence of the backbone structure and from preliminary work conducted (data not shown), it was predicted that human recombinant scFv proteins would be readily produced in soluble form. The cDNA sequence was designed to incorporate a ‘humanized’ backbone

sequence, with the CDRs remaining specific for human 5T4. The CDRs were designed from the characterized mouse scFv specific for the human 5T4 TAA (243), formerly used within this study. Amino acid substitutions were determined by aligning the previously described mouse scFv5T4 with 10 human scFv sequences to generate a consensus sequence of the V_H and V_L regions of the antibody and subsequently linking the Fv with a general peptide linker (**Figure 11**). The CDR loops specific for 5T4, and the immediate amino acids flanking the predicted loops were not altered to maintain antibody structure and specificity, predicted from topological modeling. This cDNA sequence was codon optimized for *E. coli* (**Figure 12A**), synthesized, and was subsequently used for the generation of a number of recombinant proteins (**Table 11**). The final amino acid sequence for the translated protein is found in **Figure 12B**. All subsequent results were generated using the humanized scFv5T4. Based on former experience of the murine scFv5T4 protein expression, the humanized scFv5T4 was directly inserted into the pET-32a protein expression system for genetic fusion with TrxA to increase protein solubility. The resulting genetic product was pET-32a::scFv5t4::TEV::biotin (**Figure 13A**), containing N-terminal EK cleavable TrxA and His₆ tags and a C-terminal TEV cleavable biotin tag for *in vivo* enzymatic biotinylation. The humanized scFv5T4 construct was transformed and overexpressed as a soluble protein from BL21 (DE3) and Origami B (DE3), both engineered to express BirA. The final protein, cartoon depicted (**Figure 13B**), was purified with the His₆ tag, and subsequently cleaved for removal of the N-terminal tags then dialyzed, generating a pure, biotinylated humanized scFv5T4 protein of anticipated 27 kDa size. A cartoon ribbon diagram depicts the predicted location and structure of the generated 5T4-specific CDR loops of each of the Fv regions (**Figure 13C**). The humanized scFv5T4, when fused with TrxA within the *E. coli* recombinant expression system, was successfully produced and purified as a highly soluble protein.

3.5 Engineered human scFv5T4 specifically targets the 5T4 tumour-associated antigen

To examine the specificity of the humanized scFv5T4 for binding to human 5T4, the scFv5T4 was either engineered with a biotinylated C-terminal biotin tag, to be detected with streptavidin conjugated fluorescence reagents or genetically fused to monomeric red

Figure 11. Humanized scFv5T4 sequence generation

Multiple sequence alignment of human scFv proteins (n=10) compared to murine anti-human 5T4 scFv. Conserved amino acids (dark grey) generate a consensus human backbone sequence shown below the alignment. CDR loops and the linker are labeled above their predicted regions. All sequences were taken from NCBI Protein Database (www.ncbi.nlm.nih.gov/protein) and analyzed using MacVector. References to human scFv proteins are found in the **Appendix 8**.

Structure modeled from human 80R scFv (PDB 2GHW22) (375) with 75.9 sequence identity using SWISS-MODEL (www.swissmodel.expasy.org). 5T4-targeting CDR loops of each fragment are coloured as follows: CDR1, *red*; CDR2, *blue*; CDR3, *magenta*.

fluorescent protein 1 (mRFP1) (392). Upon incubation with the human HT-29 colon cancer cells known to express 5T4 (**Appendix 7**) (194, 224), from which WiDr cells are also derived (393), scFv5T4 bound to the surface of these cells comparable to commercial anti-human 5T4 mAb (mAb5T4) (**Figure 14A**). Furthermore, both mAb5T4, as well as the scFv5T4 fragment, bound to HEK293 cells engineered to express the 5T4 antigen by transfection with pCMV6-XL5::5t4 as shown by FACS and immunofluorescence microscopy, whereas control HEK293 cells that contain only the vector (pCMV6-XL5) did not stain with either antibody (**Figure 14B-C**).

The scFv5T4 targeting for 5T4 was also determined by co-incubation of scFv5T4 and mAb5T4 with HEK293 cells engineered to express 5T4 and resulted in the same cells binding both antibodies (**Figure 15A**). Lastly, specificity for 5T4 was verified with HEK293 cells transfected with pEGFP-N1::5T4, or control vector pEGFP-N1. Microscopic analysis of GFP::5T4-expressing HEK293 cells demonstrated that scFv5T4 bound only to those cells expressing the 5T4::GFP fusion, but not to control transfected cells (**Figure 15B**). Together, these data indicate that the humanized scFv5T4 can bind specifically to human 5T4.

3.6 Generation of scFv5T4::SpeC_{D203A}

In order to target SpeC to 5T4, SpeC was genetically fused with a small flexible linker (Gly-Gly-Pro) to the humanized scFv5T4 resulting in recombinant scFv5T4::SpeC_{D203A}. For soluble protein expression, similar to the scFv5T4 alone, the fusion scFv5T4::SpeC_{D203A} construct was cloned into the pET-32a protein expression system creating an N-terminal translational fusion of TrxA and His₆ purification tags with a C-terminal translational biotin tag. For all of the final construct designs, including the scFv5T4 and non-functional fusion protein containing SpeC_{Y15A/D203A}, the pET-32a vector was altered as such that the EK cleavage site (DDDDK↓X), was replaced with a TEV protease cleavage site (ENLYFQ↓S) (368) and the C-terminal biotin tag (AviTag™, Avidity) containing a 5' gly-gly spacer was engineered to include an EK cleavage site (**Figure 16A-B**; **Table 11**). Constructs were transformed into either *E. coli* BL21 (DE3) or Origami B (DE3), both engineered to co-express pBirAcm for biotinylation. No

difference with protein yield between strains was notable (data not shown). The final fusion protein design and predicted molecular structure, once expressed and purified, is highlighted as representative images in **Figure 16C-F**.

For protein expression and purification of the fusion construct scFv5T4::SpeC_{D203A} and controls, following induced bacterial expression, the cell lysate was applied to a nickel resin column for purification with the His₆ tag and eluted with increasing concentration of imidazole. The expression of desired protein with TrxA was verified of the anticipated molecular weight of 64 kDa for fusion proteins and 39 kDa for scFv5T4 alone and purification tags were removed with autoinactivation-resistant His₇::TEV as described (368). The purified proteins were eluted in low imidazole concentrations and protein containing fractions were confirmed with expected 52 kDa and 27 kDa for fusion protein and scFv5T4 alone respectively and after buffer exchange, resulted each as soluble purified proteins (**Figure 17A**). The positive probed signal for biotin signified the successful *in vivo* biotinylation of each protein, including scFv5T4::SpeC_{D203A} and control reagents scFv5T4 and scFv5T4::SpeC_{Y15A/D203A} (**Figure 17B**). The genetic fusion of the humanized scFv5T4 and SpeC_{D203A}, with use of the multi-tag system, resulted in successful expression and purification of the potential TTS.

3.7 scFv5T4::SpeC_{D203A} and recombinant protein panel for therapeutic potential assessment

Purified recombinant proteins, including scFv5T4::SpeC_{D203A}, control reagents scFv5T4 and scFv5T4::SpeC_{Y15A/D203A}, as well as SAg_s, SpeC_{WT}, SpeC_{D203A} and SpeC_{Y15A/D203A} were all biotinylated and diluted in saline (0.9%) to the same molar concentrations for comparative use *in vitro* and *in vivo* (**Figure 18**). All proteins were of predicted 25, 27, and 52 kDa size for SAg_s, scFv5T4 and fusion constructs, respectively. The protein bands corresponded to relative concentrations of each dilution as well as represented the purity of the final product.

3.8 Human T-cell proliferation induced by scFv5T4::SpeC_{D203A}

Functionality of the SpeC_{D203A} containing scFv5T4 TTS was assessed for the ability to induce proliferation of human PBMCs compared to control proteins. scFv5T4::SpeC_{D203A} induced a dose-dependent proliferative response of human lymphocytes that was comparable to SpeC_{D203A} (**Figure 19**). Notably however, the activation induced by scFv5T4::SpeC_{D203A} remained significantly reduced compared to that of SpeC_{WT}. Furthermore, and importantly, the scFv5T4 antibody fragment alone and the double mutant fusion (scFv5T4::SpeC_{Y15A/D203A}) did not induce significant proliferative responses. This result indicated that the SpeC_{D203A} portion of the fusion is responsible for inducing PBMC activation.

3.9 Human T-cell cytotoxicity of human CRC cells induced by scFv5T4::SpeC_{D203A}

Human SpeC-reactive PBMCs were used in two assays to evaluate the TTS immunotherapeutic agent for the ability to mediate tumour cell killing. First, the human colon cancer cell line WiDr was used as the target in a 7-AAD-based killing assay. Efficient cell killing was observed after human PBMCs were stimulated with 200 nM of the agent for 48 hours, compared to wild-type SpeC and unstimulated controls (**Figure 20A**). Second, HT-29 colon cancer cells labeled with ⁵¹Cr were used as targets. Efficient cell killing was observed in a dose-dependent manner after human PBMCs were stimulated with the agent for 48 hours, and subsequently added to tumour cells with increasing effector to target (E:T) ratios (**Figure 20B**). Furthermore, the single mutant fusion (scFv5T4::SpeC_{D203A}) was more efficient than that of the similar double mutant fusion (scFv5T4::SpeC_{Y15A/D203A}) or antibody alone, but was reduced when compared with SpeC_{WT}. These data indicate that scFv5T4::SpeC_{D203A} is functional for inducing immune cell-mediated cancer cell death and that SpeC_{D203A}, scFv5T4, and scFv5T4::SpeC_{Y15A/D203A} proteins can function as precise controls to evaluate the requirement for targeting and SAg activity *in vivo*.

Figure 19. Functionality assay of recombinant protein panel for human PBMC proliferation *in vitro*

SpeC proteins were used to compare scFv5T4 alone, scFv5T4::SpeC_{Y15A/D203A} and subsequently scFv5T4::SpeC_{D203A} in the uptake of ³H-thymidine as a measure of PBMC proliferation after 4 day incubation. Data shown is one representative human donor (mean ± SEM) of five independent human donors (n=5 in triplicate). *p<0.05, **p<0.01, ***p<0.001, compared to SpeC_{WT}.

Data shown (mean \pm SEM compared to the inactive SpeC_{Y15A/D203A} control protein) is from four independent human donors each completed in triplicate. ns = non-significant, *p<0.05, **p<0.01, ***p<0.001.

3.10 Immunotherapy of established colon cancer using scFv5T4::SpeC_{D203A}

SpeC is specific for human V β 2⁺ T cells, but this SAg does not recognize mouse T cells (366). Thus, testing the SpeC-based TTS required a model utilizing human lymphocytes. Furthermore, the human 5T4 targeting scFv has minimal cross-reactivity with murine 5T4 (243). Therefore, human tumour cells expressing human 5T4 were necessary for the experiments. Based on a previously developed model (242, 335), an animal model using immunodeficient NSG mice was employed for the engraftment of 5T4⁺ human HT-29 colon cancer cells. NSG mice lack T, B, and NK cells (394) and represent an optimum mouse strain for human tumour engraftment (395, 396). Furthermore, these mice would permit the survival of transferred human immune cells (394, 397). HT-29 cells were injected ip into NSG mice and once solid tumours were palpable at 3 weeks post-injection (**Figure 21B**), treatments were initiated with iv injection (2 μ M kg⁻¹ per injection) of scFv5T4::SpeC_{D203A}, 2 hours post-ip injection of human PBMCs. Followed by 7 daily iv treatments, animals were electively euthanized 4 weeks post-treatment (**Figure 21A**). Control NSG mice did not receive PBMCs, or received PBMCs without additional treatments. Additional groups included the scFv5T4 alone, SpeC_{D203A} alone, or inactive scFv5T4::SpeC_{Y15A/D203A}.

Three weeks post-injection of the HT-29 cancer cells, further internal assessment revealed a visual mass on the mouse peritoneum of an established tumour growth at the site of injection (**Figure 21C**). Histological evaluation by H&E stain of the tumour site showed distinct tissue morphology compared to the surrounding normal peritoneal tissue (**Figure 21D**).

Change in individual animal weight was monitored throughout the experiment and results suggested that weight fluctuation in the animals receiving the scFv5T4::SpeC_{D203A} TTS was highly reduced compared to all other groups, and in general remained relatively close to original baselines, in particular near the termination of the time course (**Figure 22**). The tumour surface area was monitored using caliper measurement throughout the experiment and demonstrated little to no growth of the tumours in the

Figure 21. *In vivo* model of SpeC-based TTS therapy of established HT-29 colon cancer

A) Schematic illustration of the xenograft solid tumour model experimental timeline. NSG mice with established (3 week) ip human HT-29 tumours were injected once with human PBMC ip, followed by 8 daily intravenous injections of scFv5T4::SpeC_{D203A}, or individual controls ($2 \mu\text{M kg}^{-1}$ per injection) and sacrificed 4 weeks post-treatment. HT-29 tumour growth after 3 weeks shows palpable and visual establishment at the site of injection **B)** externally (black circle), **C)** internally on the peritoneum (dashed circles), and **D)** histologically by H&E stain of tumour (T) and surrounding normal peritoneum tissue (P). Black bar represents 2 mm.

Figure 22. Weight change of NSG mice throughout tumour establishment and TTS therapy

Weight of animals was measured throughout the experimental timeline (total = 60 days) and fluctuation evaluated from initial baseline measurement taken Day 0 and represented as individual animals. All groups contained n=4, with exception of saline treated, no PBMC control group (n=3).

scFv5T4::SpeC_{D203A} treatment group, while growth was observed in all other group (**Figure 23A**). The animals were electively euthanized at week 8 of the experiment and tumours were evaluated in a blinded fashion. Exterior overviews demonstrated evidence of the outgrowth size of the primary tumour at the injection site in all treatment groups, as well as visual metastatic sites on the upper right side of select control treated animals (**Figure 23B**). Upon internal exposure of the tumour injection site, it was evident that the human HT-29 cells established a primary solid tumour from the peritoneal cavity in all groups, which extended and attached to the inner skin surface. Gross pathology and H&E histological analysis suggested that the TTS treated animals had a reduced size in primary tumour, compared to all other treatment groups (**Figure 23C-D**), but that similar morphology and tissue composition of all primary tumours indicated that the tumours were of the same origin. Upon necropsy of the animals, tumours distant from the primary injection site at the time of sacrifice were evident within all treatment groups, however from a gross pathology overview of the peritoneal cavity, the metastatic burden was much reduced in the TTS treated animals (**Figure 24A**). Furthermore, the rate of liver metastasis was also diminished (**Figure 24B**). Of note however, the TTS treatment did not completely eliminate all metastasis as 2 out of 4 animals had evidence of at least 2 established metastases, albeit smaller comparable volume to control groups (**Table 15**). The degree of metastatic burden was visually characterized based on the location spread within the animal and also histologically analyzed by H&E stained sections to compare the composition of the metastases to the original solid tumour and to distinguish from existing healthy tissues. From this, 5 distinct locations distant from the primary tumour were defined (**Figure 24C-D**).

Of note, two animals did not reach the full experimental term of 60 days. Ethically, these animals were electively euthanized due to procedural requirements. Specifically, one male that had received the treatment of PBMCs alone followed by saline injections had a survival of 57 days. The total tumour volume of this particular animal was approximately 1615 mm³ and had 3 tumours distant to the primary solid tumour (**Table 15**). The second animal was a female that received the treatment of SpeC_{D203A}, and had a survival day of 58. The total tumour volume for this particular animal was 539 mm³ with 3 tumours

Figure 23. Size comparison of primary tumours from *in vivo* treatment groups

A) Primary tumour size was evaluated throughout the experimental timeline by external caliper measurements, individual animals represented by each graph line. Representative photographs of primary tumour at initial injection site at the time of sacrifice as **B)** overview of abdomen showing relative exterior size (dashed circles) and visible distant tumour (arrows), **C)** interior view (dashed outline) developed from peritoneal site and **D)** H&E stained histological sections (5 μ m) of respective primary tumours. Black bars represent 5 mm. All groups contained n=4, with exception of saline treated, no PBMC control group (n=3).

Figure 24. Tumour metastases from SpeC-based TTS therapy of established HT-29 colon cancer

Tumours distant from the primary injection site at the time of sacrifice shown as representative photographs of **A)** gross pathology overview of peritoneal cavity focused on tumours distant from primary site (black arrows) on the right side of animal and **B)** livers removed and analyzed for presence of tumour mass (white arrows). Primary tumour and metastases were characterized for metastatic scoring based on **C)** location within the animal (labeled i through vi), where (i) is the primary solid tumour and histologically analyzed by **D)** H&E staining sections (5 μ m) of the locations to distinguish tissues. All H&E images taken from representative saline treated animal control group (n=4) (T, tumour; P, peritoneal wall; L, liver; D, diaphragm; K, kidney). Table 15. Animal characteristics and individual data generated from *in vivo* immunotherapy TTS model with human HT-29 cancer cells

After solid tumour establishment, mice were divided by sex and subsequently grouped (n=3-4) with a random number generator to receive either scFv5T4::SpeC_{D203A} TTS, or control. Noted are: animal survival day, wet weight (g) of the primary solid tumour located at the site of initial injection site, total tumour volume (mm³), and number of visually identified metastases.

Treatment Group	Sex	Survival day	Primary tumour weight (g)	Total tumour volume (mm ³)	Number of metastases
No PBMCs/Saline	M	60	1.17	1353.5	4
	M	60	0.71	1887.5	5
	M	60	2.50	2677.6	3
Saline	M	57	1.44	1615.8	3
	M	60	0.38	1932.9	2
	M	60	0.35	1052.0	4
	F	60	0.63	642.3	2
SpeC _{D203A}	M	60	1.17	2046.3	2
	M	60	1.02	4753.7	4
	F	58	0.30	539.2	3
	F	60	1.07	2058.6	3
scFv5T4	M	60	1.08	5893.3	2
	M	60	1.89	2011.8	3
	F	60	0.48	674.5	4
	F	60	0.42	673.7	3
scFv5T4::SpeC _{Y15A/D203A}	M	60	1.12	1951.9	4
	M	60	0.62	2020.1	2
	M	60	0.81	1332.2	2
	F	60	0.18	938.3	3
scFv5T4::SpeC _{D203A}	M	60	0.34	380.0	2
	M	60	1.07	900.8	2
	M	60	0.53	123.9	0
	F	60	0.49	400.6	1

distant to the primary solid tumour (**Table 15**). No other abnormalities were visually noted during the necropsy other than dehydration, and weight loss. Furthermore, one male that had received the TTS treatment, but not the full dose due to initial injection technique, had a notable larger total tumour volume as well as primary tumour size (**Table 15**). A potential sex bias was also noted within the model as the male animals responded better to overall tumour growth from human HT-29 cancer cells in comparison to the females within this strain of mice (**Table 15**).

Overall, this experiment demonstrated a dramatic reduction in the total tumour volume and metastatic burden after treatment with scFv5T4::SpeC_{D203A} that was significantly different from mice that did not receive PBMCs, sham treated mice (saline), and mice treated SpeC_{D203A} alone, or with control treatment scFv5T4::SpeC_{Y15A/D203A} (**Figure 25A-B**). Importantly, there were no differences in tumour volumes or number of metastases between mice that received PBMCs alone and the different control reagents (**Figure 25A-B**).

Immunohistochemistry of the solid primary tumours was performed comparing the TTS treated animals to the non-immune inducing scFv5T4::SpeC_{Y15A/D203A} treatment group. The rate of cellular proliferation, blood vessel formation, as well as cellular apoptosis showed no significant difference among the two treatment groups. Furthermore, there was no distinction between the numbers of CD3⁺ cells within the solid tumours at this time point (**Figure 26A-B**).

Together, these data indicate that although there was no specific differences in the IHC of the solid primary tumours, the TTS treated group demonstrated an overall weight maintenance and dramatic reduction in the total tumour volume with a significant reduction in the total metastases score compared to control treatment groups.

Figure 25. Tumour burden from SpeC-based TTS therapy of established HT-29 colon cancer

Twenty-eight days post-final injection, **A)** final tumour volume was measured and **B)** metastatic score evaluated. All groups contained n=4, with exception of saline alone control (n=3). *p<0.05, **p<0.005.

Figure 26. Immunohistochemistry profiles of TTS treated primary HT-29 tumours

Twenty-eight days post-final injection, primary tumours were excised, sectioned (5 μm) and assessed by IHC. Similar histological profiles are shown as **A)** representative images of primary tumour sections and **B)** quantification of staining from animals receiving either TTS or control treatments and stained for proliferative marker Ki67, endothelial cell marker vWF, apoptosis by TUNEL, and T cell marker CD3. All sections were counterstained with nuclear stain DAPI and imaged with fluorescence microscopy. White bars represent 50 μm . Images are representative of 1 stained section from each animal (n=4). Quantification was generated with blinded counting of positive stains from 5 random high-power fields (hpf) per section per animal (n=20 per stain per treatment group; mean \pm SEM).

CHAPTER 4: DISCUSSION

T lymphocytes are recognized as one of the most important immune cells involved in tumour regression within the field of cancer immunotherapy, and bacterial SAgS are among the most potent naturally occurring specific activators of T cells. Thus, the appropriation of SAgS to target cancer cells (309) has received significant attention and has become very promising in the advancement of targeted immunotherapies. Of particular interest are those where mAbs are used (338, 342) and encouragingly, TTS therapeutics are now being evaluated in human clinical trials (323-325, 337, 338, 342, 348).

In Canada, cancer is the leading cause of death, responsible for nearly 30% of all deaths and in recent reports, it is expected that new cases will dramatically rise over the next 15 years due to the increasing aging population (3). In this work, the focus was on colorectal cancer, one of the four major contributors to new cancer diagnose. This cancer accounts for more than half of all cancers within Canada and is the second and third most common cause of cancer death for males and females, respectively (3). With few clinical symptoms evident until the onset of stage III or IV, this carcinoma is difficult to diagnose. As such, ~20% of diagnosed patients present with inoperable CRC and ~25% of operable patients will develop metastases due to recurrence, resulting in a relatively high overall mortality rate (~45%) for CRC (10, 15). It is clear that advances in treatment, diagnosis, and prevention strategies of this carcinoma are of considerable importance.

Successful treatments of an invasive cancer, in addition to addressing the primary site, must also direct targeted effects towards the distant metastases, therefore mAbs have been employed to direct targeted cytotoxic responses (398, 399). mAbs of murine origin and mouse/human chimeras have been used either alone or linked to a therapeutic agent with encouraging results, of which some have been FDA approved for use in the clinic (*e.g.* ibritumomab tiuxetan, rituximab, cetuximab) (400). However, concerns have arisen using whole murine and chimeric mAbs in humans. Firstly, the whole murine mAbs can induce HAMA responses (153) along with systemic toxicity due to the requirement for high doses for effective treatment (323, 337). Furthermore, it has been found that surface molecule specific whole mAbs do not efficiently penetrate solid tumours (401), are not uniform in final biodistribution, and can have high serum levels leading to toxicities

(183). Engineering smaller antibodies can minimize these issues associated with whole mAbs and this has led to the development of recombinant molecules such as Fab and scFv fragments. This results in much smaller, tumour-penetrating molecules in particular for scFv fragments, that retain the binding activity of the full IgG molecule (401, 402). However, scFv fragments have decreased stability and tumour retention (183), as well as a shorter half-life in serum and are cleared more rapidly compared to larger fragments (403). An ideal tumour-targeting reagent would be of intermediate size which could provide rapid tissue penetration, high target retention, and rapid blood clearance (183). For example, this sized reagent can be generated by incorporating the scFv into a complex molecule such as a fusion with an immune stimulatory molecule (402).

The tumour-associated antigen, 5T4, is of particular interest for advancement of targeted immunotherapeutics (226) as its expression is restricted on normal adult tissues, but it is upregulated on an array of carcinomas, including CRC (196). Although this antigen is expressed throughout cancer progression, it has been most frequently detected on malignant cells with no evidence of downregulation (198) and has been associated specifically with metastasis in CRC (199). Indeed, further investigation of this antigen demonstrated that upon expression it is involved in decreasing cellular adhesion, influencing cytoskeletal organization, and promoting cell motility and migration (223, 224). As a result, poor clinical outcome in some cancers is associated with these altered cell properties (223). 5T4 has been the target of a number of developing immunotherapies, including chimeric antigen receptors (404), antibody-drug conjugates (241), a vaccine undergoing clinical trials (405-407), as well as TTSs (338, 343), all demonstrating promising results.

An effective targeted immunotherapeutic will direct activated cytotoxic lymphocytes to the tumour for eradication. SAGs, microbial toxins produced primarily by staphylococcal and streptococcal species, are known for having some of the most potent immunostimulatory properties. Of the streptococcal SAGs presently studied, SpeC is the best characterized and has been extensively described in terms of both structure (272, 285, 365) and function (277, 286, 366-369) for engagement of host receptors. A complete binding map for specific interactions between SpeC and TCR V β 2.1 (277, 368), as well

as the high-affinity zinc-dependent binding interface with MHC II β -chain (369) and low-affinity MHC II α -chain binding interface (286) of this SAg has been established. With this knowledge, strategic SAg mutations may be applied to modulate the T cell stimulatory capacity of this SAg, generating, to the best of our knowledge, the first streptococcal SAg to be employed in TTS immunotherapeutics, enabling expansion of the current TTS repertoire. Specifically, to prevent high-affinity and non-specific binding of MHC II molecules, Asp²⁰³, a residue involved in the coordination of the zinc ion of the high affinity site (272) can be altered to Ala such that the potent immune stimulation, and therefore toxicity, of the SAg is reduced (286, 369). Indeed, this study provided further evidence that Asp²⁰³, when altered to Ala, reduced a stimulated human immune response (**Figure 8**). Importantly however, it was also demonstrated that this reduced stimulation was still sufficient for the ability to induce immune-mediated cancer cell death (**Figure 9**). Similarly, the high-affinity MHC II binding site of the SAg SEA has been characterized (328) and a mutation of Asp²²⁷ to Ala has been shown to reduce systemic side effects (331, 335, 338). As a result, this mutational design has also been incorporated into TTSs currently undergoing human clinical trials. This suggested that this particular variant of SpeC would be beneficial in the overall development of TTSs while reducing off-target activation of the immune system. Further, within the SAg SpeC, Tyr¹⁵ has been reported to be a critical residue in the interaction with the TCR binding interface leading to T cell activation (368). As such, this residue when mutated to Ala, in combination with the altered Asp²⁰³, can be used for the generation of precise control reagents that maintain structural integrity and targeting, but lack immune stimulation activity. The importance of Tyr¹⁵ for the engagement of the TCR was further supported by this work, both as a single and a double mutant SpeC variant, demonstrating reduced and absence of induced immune stimulation, respectively (**Figure 8, 9**).

As indicated, the concept for using a TTS as an immunotherapeutic is not novel (309), and has great potential for future cancer immunotherapy. Promising results from such TTSs have been demonstrated in both murine studies (322, 335, 341) as well as human clinical trials (323, 337, 338, 342, 348) where a murine Fab antibody portion, targeting a TAA is fused to SEA. The most developed of these TTSs specifically targets the TAA

5T4, and in preclinical studies, a reduction in the number of tumours present, as well as a reduction in overall tumour mass, with the absence of obvious systemic side effects was demonstrated (335). Modifications were engineered within the SAg portion of the TTS for use in human clinical trials to reduce systemic immune activation (338) as well as alterations designed to reduce host antibody recognition in the most current version, naptumomab estafenatox (ABR-217620; Fab5T4-SEA/E-120) (242, 339) for use in Phase I (342, 343) and subsequent Phase II/III trials (348). Although this treatment showed promise, aside from T cell activating properties, staphylococcal SAg are also the agents of staphylococcal food-borne illness (261), a property not shared among the streptococcal SAg (253, 262). This was noted from side effects seen in Phase I and II/III clinical trials that included nausea, vomiting, and diarrhea (337, 338, 342). To date, TTSs have been exclusively built using members of the SE class of SAg, all sharing emetic properties. Evidence also suggested that the murine Fab portion had led to high levels of HAMA after multiple cycles of treatment (337), and unexpectedly, in recent Phase II/III trials, patients had higher than anticipated baseline levels of anti-SEA/E-120 antibodies, which may have contributed to suboptimal therapy (209, 346, 348). Collectively, this information led to the design of a novel “next generation” TTS composed of a scFv antibody fragment directed against a TAA and a potent streptococcal T cell activating SAg. More specifically, within this study, a scFv directed against human 5T4 fused to the streptococcal SAg prototype, SpeC, was developed and preclinically tested *in vitro* and *in vivo*.

The earliest form of the TTS molecule consisted of a previously described murine scFv antibody specific for human 5T4 (243), genetically fused by a short peptide linker (Gly-Gly-Pro) to an altered SpeC containing an Asp²⁰³ to Ala mutation (scFv5T4::SpeC_{D203A}) (372, 373). In addition, the fusion protein was further constructed to contain an Ala mutation at residue 15, replacing the endogenous Tyr, to generate a precise non-immune stimulating control reagent (scFv5T4::SpeC_{Y15A/D203A}) (373). Expression of the recombinant fusion proteins from the *E. coli* bacterial system proved successful, however unlike the typical SAg portion alone (**Figure 7**), the proteins formed insoluble, misfolded aggregates termed inclusion bodies. Over-expression of heterologous proteins in *E. coli* is frequently hindered by the formation of inclusion bodies, and is incidentally common

amongst scFv proteins (408-411). As a result, isolating and refolding of proteins from inclusion bodies has become an essential requirement in the study of proteomics and this method has been quite useful as a means of recovering functional proteins (412). However, in protein expression studies, optimization of the host culture conditions, or the fusion to a large affinity tag can often prevent the necessity of isolating these misfolded aggregates (389). Within this study, the preparation and refolding methods used for inclusion bodies, although successful, were not ideal for the downstream processing requirements of large-scale therapeutic production; therefore, the optimization of protein expression continued to be the strategy to obtain a soluble, bioactive protein. Notably, alternative expression organisms may be also used to prevent inclusion bodies, such as yeast (*Saccharomyces cerevisiae*) (390) or eukaryotic cell lines (413, 414), however, would prove to be considerably laborious, and non-cost and -time effective when compared to the well-established, easily manipulated, and high biomass-to-cost ratio (389) that could be obtained from the *E. coli* platform.

Over the course of this study, several considerations and alterations were applied to the genetic construct containing the murine scFv5T4 fused to SpeC_{D203A}, as well as to the expression and purification methods for improved protein yield. Of these, a highlight included the addition of a C-terminal high-affinity unique peptide tag (biotin tag; AviTag™ Technology, Avidity) to use the strong interaction of biotin and avidin with aims to enhance the sensitivity of protein capture and increase protein detection. Although this tag was not advantageous to the overall purification of the product, this technology was extremely useful for enhanced detection sensitivity of the expressed constructs. Additionally, the solubility of a target protein can be enhanced by fusion with a highly soluble carrier protein such as maltose-binding protein (MBP) or a hydrophilic tag such as a transcription termination anti-termination factor (NusA), TrxA, or protein disulfide isomerase I (DsbA) (380). However, hydrophilic tags must be used in combination with a smaller affinity tag, for example His₆ or FLAG, within an expression system for purification (380). This multi-tag approach has become a common tactic to address solubility issues (380, 381) and since recognized, have become widely commercially available. Notably, TrxA has been widely used to increase protein solubility (387-389), including specifically for scFv constructs (390, 391) and therefore,

efforts focused on increasing protein solubility for scFv5T4::SpeC_{D203A} generated an expression system in which TrxA was fused to the N-terminus of the genetic constructs, along with a His₆ tag for affinity purification. Through all experimental attempts and efforts to optimize and increase soluble protein expression, it was clear that sufficient yield of the murine scFv5T4, as a soluble product, remained a significant challenge.

Due to the limitations associated with generating the murine scFv5T4, an alternate approach was applied to generate a recombinant soluble molecule for large-scale production as well as to further develop the 5T4-specific streptococcal TTS by designing a ‘humanized’ scFv5T4 antibody fragment to also prevent HAMA responses. Indeed, the approach of genetically grafting the 5T4-specific CDR loops from the murine fragment onto a ‘humanized’ scFv backbone (**Figure 11, 12**) successfully generated and produced a highly soluble protein when fused with TrxA within the *E. coli* expression system.

Evaluations of the humanized scFv5T4 demonstrated specific 5T4-targeting ability *in vitro* (**Figure 14, 15**) and provided further preclinical evidence for 5T4 as a potential TAA for targeted immunotherapy. Although this work highlights the binding capabilities of the humanized scFv5T4 to its target 5T4, further evaluation to conclusively determine the specificity and binding affinity would be beneficial. For example, while the original 5T4-targeting mAb was evaluated for distribution on normal and neoplastic tissues (196, 243), verification that the humanized scFv5T4 retains the consistent non-specific binding to various cell and tissue types would be of value. Similarly, further verification of the high affinity binding measured for the murine scFv5T4 ($K_d = \sim 10^{-9}$) (243) of the altered humanized scFv5T4 would advance the application of these targeting therapeutics. Although there has not been any evidence to date of 5T4 downregulation throughout cancer progression, characterization of the downstream effects as a result of binding from this targeted scFv fragment would be of value for elucidating the cellular role and consequence of the potential TTSSs.

Upon genetic fusion of the humanized scFv5T4 and SpeC_{D203A}, with the consistent design of the multi-tag approach, successful expression and purification of the potential TTS was generated (**Figure 17**). Furthermore, the precise control reagents scFv5T4 alone, as well

as the non-immune stimulating scFv5T4::SpeC_{Y15A/D203A} were produced. Further *in vitro* work provided evidence that the Asp²⁰³ to Ala mutation contained with the TTS reduced SAg-induced activity (**Figure 19**) but was sufficient in the ability to induce immune-mediated colon cancer cell death (**Figure 20**). Importantly, immune stimulation was not demonstrated by the control reagents, scFv5T4 and scFv5T4::SpeC_{Y15A/D203A}, indicating that SAg activity was required for tumour cell killing. This was the first account, to our knowledge, of a streptococcal SAg-based TTS inducing *in vitro* cytotoxicity towards colon cancer.

As SpeC does not recognize murine T cells (366), and the human 5T4 targeting scFv has minimal cross-reactivity with murine 5T4 (243), limited value would come from the use of a syngeneic murine model. Therefore, based on a previously developed model (242, 335), a xenogeneic model consisting of the engraftment of 5T4⁺ human HT-29 colon cancer cells and the transfer of human immune cells were applied to immunodeficient NSG mice. NSG mice lack T, B, and NK cells (394) and represent an optimum mouse strain for human tumour engraftment (395, 396) and also permit the survival of human immune cells (394, 397). Herein, it was demonstrated that the soluble recombinant fusion protein scFv5T4::SpeC_{D203A} was able to specifically target 5T4 to elicit a T cell response that substantially reduced tumour burden *in vivo*. Importantly, a model of established tumours was used in order to robustly test the SpeC-based TTS. Within this model however, for reasons undetermined, there was a disparity of overall tumour growth amongst the male and female animals and though the males supported a more robust establishment of HT-29 cancer cells, among the matched groups (**Appendix 6**), the trend of results nevertheless remained. Importantly, the TTS treatment group at this dose had no observable side effects on animal health (**Figure 22**), suggesting that the treatment may be safe for further downstream evaluations and continued applications.

In this model, while the primary tumours did not appear to regress, the data clearly demonstrated that scFv5T4::SpeC_{D203A} TTS was able to prevent further tumour growth as well as the development of peritoneal metastases. Expectedly however, the PBMC sham treatment group, as well as the control reagents, also had a marked decrease in overall tumour burden when compared to the saline control group (**Figure 25**). This can be

attributed to an allograft response caused by the mismatch of HLA between the donor PBMCs and the HT-29 cancer cells.

In summary, as scFv5T4::SpeC_{D203A} and SpeC_{D203A} showed similar activity *in vitro* (**Figure 19**), the inability of SpeC_{D203A} to impact tumour size or metastatic disease indicates that the scFv5T4 moiety of the fusion protein was required for *in vivo* targeting of 5T4⁺ HT-29 cells (**Figure 25**). Likewise, the inability of scFv5T4 alone, or the inactive scFv5T4::SpeC_{Y15A/D203A} fusion to show any measurable impact (**Figure 25**) demonstrates that T cell-dependent SAg activity was also required for tumour cell killing. Importantly, though the incorporation of the altered SAg was designed to decrease systemic T cell activation by reducing MHC II binding by the TTS, in the 5T4Fab-SEA/E-120 TTS, the mouse Fab moiety has been shown to effectively replace the MHC II binding domain such that T cells are efficiently activated when artificially 'presented' by the tumour (340). It is suspected that the humanized scFv5T4 moiety here played a similar role contributing to the dramatic reduction in tumour volume and metastatic disease. Closer analysis suggested that although the primary tumours of TTS treated (scFv5T4::SpeC_{D203A}) and the non-immune stimulating control (scFv5T4::SpeC_{Y15A/D203A}) did not display any immunohistological distinctions (**Figure 26**), it is anticipated that differences may be noted among the metastatic sites within degree of apoptosis, immune infiltration, and tumour development. The reduction in overall metastases in TTS treated animals is presumed to be due to the enhanced immune activation at these localized areas, however further investigation is warranted beyond the 'snapshot' captured from the primary tumours.

While this xenograft model of established human HT-29 colon cancer cells and engrafted human PBMCs clearly demonstrated an overall reduction in tumour burden with TTS treatment, there are also a number of limitations for consideration. Firstly, as the immune system is artificially delivered by means of an intraperitoneal injection of isolated human PBMCs, this model lacks the ability to evaluate the TTS to cause immune cell recruitment and migration for a localized anti-tumour response. Future experimentation may include intravenous delivery of the PBMCs to evaluate this response and any systemic effects that may be elicited by the TTS. Furthermore, as PBMC preparations are

used, the polymorphonuclear cell (PMN) populations, in general, are absent and therefore the full immune effect of the TTS is unable to be fully evaluated within this model. Lastly, this model limits the extensive interactions between the developing tumours and immune system, lacking the effects of immunoediting and resulting gradual heterogeneity development along with the generated immunosuppressive microenvironment typical of the tumour. Recently, much work has been achieved to meet the challenging need of new therapeutic treatment evaluation in the development of humanized NSG mice for immuno-oncological studies (415). For some time, these animals have been known to be able to support the development and function of multiple aspects of human immunity, including both myeloid and lymphoid cells from engraftment of human hemopoietic stem cells (394). As well, further evidence demonstrates that these humanized mice also allow the co-engraftment of a wide range of heterologous, allograft human tumours, providing a number of options for animal models that can act as the preclinical bridge for current immuno-oncology therapies (415).

Although the specific mechanisms of TTS-induced anticancer immunotherapy have not been fully elucidated, it can be speculated from the *in vivo* model that it is the combined efforts of both the SAg as well as the targeting moiety. From studies focused on elucidating the role of 5T4, it has been recently shown with mouse embryonic cells that CXCR4/CXCL12 chemotaxis, signaling important for cell mobilization, can be blocked with mAbs to 5T4 *in vitro* (227). Importantly, treatments to block 5T4 antigen *in vivo* was also able to prevent the spread of human 5T4⁺ B-ALL cells (227), demonstrating that the observed reduction may be related to 5T4 function in regulating chemokine or signaling pathways. Although this effect has not been specifically observed to date within preclinical studies of TTSs, this study inclusive, the ability to have comparative analysis with 5T4-targeting alone treatments (scFv5T4 or scFv5T4::SpeC_{Y15A/D203A}), was generated. Based on this early work, consideration of antibody targeting and downstream effects of blocking 5T4 signaling merits further investigation.

Secondly, the ability of bacterial SAgS to induce cytokines that maintain T-cell activity as well as those that are tumouricidal are important features (308, 309, 320). Key

inflammatory cytokines for these specific effects are IL-2 and IFN- γ , the hallmarks of T cell activation, of which SAgS in general, including SpeC (248), are known to induce. Indeed, in previous TTS experimental preclinical models, in addition to perforin-mediated cytotoxicity, release of IFN- γ as well as TNF- α has been shown to be particularly important for anticancer effects (320, 355). The initial release of these SAg-induced cytokines will lead to induced proliferation of CD4⁺ and CD8⁺ T cells (416), in particular CTLs and NK cells. Early SEA-based TTS work *in vivo* demonstrated a massive influx of both CD4⁺ and CD8⁺ T cells into the targeted tumour, suggestive of the induced release of T cell specific chemokines to encourage cellular trafficking at the tumour site and when T cells were depleted, a complete abrogation of therapeutic effect was observed (320). In recent clinical studies with Naptumomab estafenatox (ABR-217620) therapy, select patient sampling also included PBMCs and analysis of associated changes in lymphocyte subsets (348). Most notable was the consistent expansion of TTS specific CD4⁺ and CD8⁺ T cells in peripheral blood that coincided with pronounced IL-2 production (348). Furthermore, in additional clinical studies with the same treatment, responding patients demonstrated that T cells infiltrate tumours (342). These secondary events, in addition to an overall heightened immune response, are also thought to be important in killing subsets of neighboring cancer cells that may not express the specific TAA (335). Based on evidence from the SEA-based clinical trials, it may be speculated that TTSs act mainly by induction of T cell activation, proliferation and maturation into effector cells and secondly, by recruitment and T cell killing of the tumour. Although the specifics of cytotoxic mechanisms directed toward CRC have yet to be studied for streptococcal SAgS, based on the similar T cell activation profiles of staphylococcal and streptococcal SAgS, it is predicted that the mechanism of immune-mediated cancer cell death of SpeC will be comparable to SEA-based TTS. Future analysis of serum samples collected from animals within this study may shed light on the cytokine profile induced by the humanized scFv5T4::SpeC_{D203A}. To ultimately determine the types and quantities of cytokines released for future therapeutic development would be of importance, in particular, should tailoring the response be desired of streptococcal based-TTSs. Of note however, compared to native SAg, a higher dose may be required to accommodate for the reduced binding capabilities of SpeC_{D203A} to MHC II within patients as demonstrated in

this work (**Figures 8, 9, 19, 20**) and in Phase I dose studies using comparable SEA_{D227A} (342). Nonetheless, even with the limited V β 2 repertoire of SpeC (283, 366), the potent response of the induced cytotoxic T cells, in combination with the targeting moiety, still resulted in a dramatic reduction in tumour volume and metastatic disease within preclinical assessment (**Figure 25**).

There are some potential advantages, and disadvantages, in using TTSs for tumour immunotherapy that require further consideration. As described, the use of a mouse derived antibody as a targeting motif may result in HAMA responses since murine mAbs are highly immunogenic (153). This may limit the utility of subsequent treatments and thus the use of a humanized scFv containing TTS as developed in this work may provide clinical benefit. Second, bacterial SAgS are produced by bacteria that are often frequent colonizers in humans and thus many individuals will have pre-existing and neutralizing antibodies to many streptococcal and staphylococcal SAgS (417, 418). To overcome this issue, it is foreseen in future generations of 'combinatorial' TTSs with different SAgS, a panel could be generated such that individual patients could be screened for SAg neutralizing antibodies and then treated with an appropriate TTS. Early work in this area demonstrated that multiple SEs are capable of inducing T cell-mediated cytotoxicity against cancer cells (310); however, it is envisioned that the SAg panel would include members from the Group IV and Group V subclass of SAgS (248, 253, 377), as these subclasses contain only streptococcal SAgS and SEI SAgS, that collectively lack the emetic properties of the bona fide SEs (253, 262). Indeed, the SEI-M, SEI-N, and SEI-O SAgS from the *egc* have recently been demonstrated to induce T cell dependent killing of a broad panel of human tumour cells *in vitro* (419). Also, human serum levels of neutralizing antibodies against the *egc* SEs have been shown to be lower than those directed against the 'classic' SEs (264). In addition, each of the Group IV and V SAgS have a well-defined zinc-binding motif (248) involved in high-affinity MHC II binding (272, 273) that can be targeted for appropriate mutagenesis to prevent systemic immune activation as shown here and previously for SEA (328, 331). In anticipation of designing a panel of TTSs, the fusion construct was specifically designed within this study to include an additional restriction enzyme digestion site on the C-terminal end of the scFv5T4 fragment. This not only enables genetic replacement of SpeC with SAg

variations with the option to allow for ‘fine-tuning’ of the desired immune response, but it may also prove particularly beneficial in the future in the design of a TTS panel with a diversity of SAGs and/or targeting scFvs for a variety of TAAs. Indeed, an additional TTS has recently been designed, composed of a humanized scFv directed at the human TAA Her2/neu [designed from the Fab Herceptin (420)] and a Group VI SAG, SmeZ, with a high-affinity site mutation Asp²⁰⁴ to Ala for reduction in systemic immune cell activation in preclinical experimentation (McCormick laboratory, unpublished).

A third important limitation to TTS immunotherapy is that bacterial SAGs are well known to induce V β -specific T cell deletion or anergy (294), which includes CD8⁺ T cells (296). Thus, repeated administration of the same TTS in humans may result in populations of non-responsive T cells. However, using the B16 model of melanoma, a sufficient resting period between treatments did restore immune responsiveness resulting in prolonged survival with repeated cycles of therapy (322). Nevertheless, this limitation could potentially be circumvented by the use of multiple SAGs with different V β profiles. From this work, CD3⁺ T cells remained engrafted within the primary tumour after TTS treatment (**Figure 26**). Further investigation warrants the potential activation of this subset of T cells for full eradication of the cancer cells with either a repeated dose of SpeC-based TTS or an alternative V β -targeting SAG TTS. From the prospective of the TAA, similarly, a remaining and important issue with TTS immunotherapy is the targeting of a single TAA. An effective TTS would likely invoke a form of cancer immunoediting (71), and simple down regulation of the TAA may provide a means of escape. The TTS immunotherapy platform offers an approach for targeting a number of different TAAs, and it will be of future interest to engineer and combine TTSs that utilize SAGs with different V β profiles.

As with the majority of cancer therapeutics, it is anticipated that the TTS alone would not be sufficient to eradicate the entirety of the cancer. mAbs that target VEGF (*e.g.* Bevacizumab) and EGFR (*e.g.* Cetuximab or Panitumumab) have shown benefit in patients with mCRC (55, 56, 58), and a future area of interest would be to test TTS combination therapies with these treatments. Immunotherapies such as the CARs targeting CD19 have now demonstrated some extraordinary clinical outcomes in patients

with advanced B cell leukemia (119, 123, 421, 422). In addition, blocking immune system regulatory 'checkpoints' with antibodies (*e.g.* anti-CTLA-4 or anti-PD-1) is promising (423). In preclinical combinational therapies, SEA-based TTS directed at colon carcinoma antigen C215 has been shown to achieve synergistic antitumour effects, prolong long term survival and maintain compatibility with both immune modulators IL-2 (357) and IFN- α (344) and the well-established cytostatic drug docetaxel (341). Furthermore, this TTS in combination with antagonistic CTLA-4 mAb, demonstrated a favorable shift in the ratio between T effector and Treg cells in preclinical studies and that a CTL response was significantly prolonged, enhancing antitumour activity (361).

To conclude, within this work, a novel TTS treatment was designed and successfully generated as a soluble recombinant fusion protein in a bacterial protein expression system. The TTS fusion protein consisted of a humanized scFv targeting 5T4 and an altered SAg SpeC as a prototype to reduce systemic immune effects. Following *in vitro* evaluations, the scFv5T4 specifically targeted 5T4 and the TTS was shown to mediate PBMC activation and cytotoxicity of colon cancer cells. Lastly, the TTS demonstrated overall reduced total tumour volume and metastases burden in an established colon cancer *in vivo* model. This was, to our knowledge, the first streptococcal SAg to be employed in TTS immunotherapeutics, enabling the expansion of the current TTS repertoire. From this work, a platform of TTSs may be constructed, offering an additional approach for targeting a number of different TAAs, and combinations with alternate SAgS targeting various V β subsets of T cells. Additionally, this TTS may have prospective use in combinational therapies, overall increasing the selection of treatments to achieve synergistic and optimal anticancer effects. Evidence suggests that TTSs may represent a future 'off-the-shelf' therapy to harness V β -specific subsets of T cells without the requirement for manipulation of autologous T cells. This mode of action may be highly effective against tumours, in particular metastases, and those considered to be non-immunogenic. This work may help to guide the 'next generation' of TTSs for tailored cancer immunotherapy.

APPENDICES

Appendix 1. Human ethics approval certification

Office of Research Ethics

The University of Western Ontario
 Room 4180 Support Services Building, London, ON, Canada N6A 5C1
 Telephone: (519) 661-3036 Fax: (519) 850-2466 Email: ethics@uwo.ca
 Website: www.uwo.ca/research/ethics

Use of Human Subjects - Ethics Approval Notice

Principal Investigator: Dr. J. McCormick

Review Number: 09911E **Revision Number:** 3

Review Date: September 9, 2009 **Review Level:** Expedited

Protocol Title: Molecular architecture of streptococcal superantigen/T cell receptor interactions

Department and Institution: Microbiology & Immunology, Lawson Health Research Institute

Sponsor: CIHR

Ethics Approval Date: September 9, 2009 **Expiry Date:** September 30, 2014

Documents Reviewed and Approved: Revised Study End Date

Documents Received for Information:

This is to notify you that The University of Western Ontario Research Ethics Board for Health Sciences Research Involving Human Subjects (HSREB) which is organized and operates according to the Tri-Council Policy Statement: Ethical Conduct of Research Involving Humans and the Health Canada/ICH Good Clinical Practice Practices: Consolidated Guidelines; and the applicable laws and regulations of Ontario has reviewed and granted approval to the above referenced revision(s) or amendment(s) on the approval date noted above. The membership of this REB also complies with the membership requirements for REB's as defined in Division 5 of the Food and Drug Regulations.

The ethics approval for this study shall remain valid until the expiry date noted above assuming timely and acceptable responses to the HSREB's periodic requests for surveillance and monitoring information. If you require an updated approval notice prior to that time you must request it using the UWO Updated Approval Request Form.

During the course of the research, no deviations from, or changes to, the protocol or consent form may be initiated without prior written approval from the HSREB except when necessary to eliminate immediate hazards to the subject or when the change(s) involve only logistical or administrative aspects of the study (e.g. change of monitor, telephone number). Expedited review of minor change(s) in ongoing studies will be considered. Subjects must receive a copy of the signed information/consent documentation.

Investigators must promptly also report to the HSREB:

- a) changes increasing the risk to the participant(s) and/or affecting significantly the conduct of the study;
- b) all adverse and unexpected experiences or events that are both serious and unexpected;
- c) new information that may adversely affect the safety of the subjects or the conduct of the study.

If these changes/adverse events require a change to the information/consent documentation, and/or recruitment advertisement, the newly revised information/consent documentation, and/or advertisement, must be submitted to this office for approval.

Members of the HSREB who are named as investigators in research studies, or declare a conflict of interest, do not participate in discussion related to, nor vote on, such studies when they are presented to the HSREB.

Appendix 2. Animal ethics approval certification

AUP Number: 2012-026

PI Name: McCormick, John

AUP Title: Next Generation Superantigen-based Immunotoxins For Cancer Therapy

Approval Date: 09/28/2012

Official Notice of Animal Use Subcommittee (AUS) Approval: Your new Animal Use Protocol (AUP) entitled "Next Generation Superantigen-based Immunotoxins For Cancer Therapy" has been APPROVED by the Animal Use Subcommittee of the University Council on Animal Care. This approval, although valid for four years, and is subject to annual Protocol Renewal.2012-026::1

1. This AUP number must be indicated when ordering animals for this project.
2. Animals for other projects may not be ordered under this AUP number.
3. Purchases of animals other than through this system must be cleared through the ACVS office. Health certificates will be required.

The holder of this Animal Use Protocol is responsible to ensure that all associated safety components (biosafety, radiation safety, general laboratory safety) comply with institutional safety standards and have received all necessary approvals. Please consult directly with your institutional safety officers.

Submitted by: Copeman, Laura
on behalf of the Animal Use Subcommittee
University Council on Animal Care

The University of Western Ontario
Animal Use Subcommittee / University Council on Animal Care

Appendix 3. Clinical trial outcome definitions

Acronym	Outcome	Definition ^a
AE	Adverse event	An unexpected medical problem that happens during treatment with a drug or other therapy. Adverse events do not have to be caused by the drug or therapy, and they may be mild, moderate, or severe
CR	Complete response	The disappearance of all signs of cancer in response to treatment. This does not always mean the cancer has been cured; also called complete remission
DFS	Disease-free survival	The length of time after primary treatment for a cancer ends that the patient survives without any signs or symptoms of that cancer
DLT	Dose-limiting toxicity	Describes side effects of a drug or other treatment that are serious enough to prevent an increase in dose or level of that treatment
DRR	Durable response rate	The length of time (usually displayed in months), that a partial or complete response is observed, as a result of treatment
MTD	Maximum tolerated dose	The highest dose of a drug or treatment that does not cause unacceptable side effects
OS	Overall survival	The length of time from either the date of diagnosis or the start of treatment, that patients diagnosed with the disease are still alive
OSR	Overall survival rate	The percentage of people in a study or treatment group who are still alive for a certain period of time after they were diagnosed with or started treatment. The overall survival rate is often stated as a five-year survival rate
PFS	Progression-free survival	The length of time during and after the treatment that a patient lives with the disease but it does not get worse
QoL	Quality of life	The overall enjoyment of life. Many clinical trials assess the effects of cancer and its treatment on the quality of life. These studies measure aspects of an individual's sense of well-being and ability to carry out various activities
PR	Partial response	A decrease in the size of a tumour, or in the extent of cancer in the body, in response to treatment
PK	Pharmacokinetics	The activity of drugs in the body over a period of time, including the processes by which drugs are absorbed, distributed in the body, localized in the tissues, and excreted

^aModified from National Cancer Institute Dictionary of Cancer Terms (<http://www.cancer.gov/>)

Appendix 4. Clinical trial phase definitions

Phase	Definition ^a
0	Exploratory study involving very limited human exposure to the drug, with no therapeutic or diagnostic goals (for example, screening studies, microdose studies)
I	Studies that are usually conducted with healthy volunteers and that emphasize safety. The goal is to find out what the drug's most frequent and serious adverse events are and, often, how the drug is metabolized and excreted
II	Studies that gather preliminary data on effectiveness (whether the drug works in people who have a certain disease or condition). For example, participants receiving the drug may be compared with similar participants receiving a different treatment, usually an inactive substance (called a placebo) or a different drug. Safety continues to be evaluated, and short-term adverse events are studied.
III	Studies that gather more information about safety and effectiveness by studying different populations and different dosages and by using the drug in combination with other drugs
IV	Studies occurring after FDA has approved a drug for marketing. These including postmarket requirement and commitment studies that are required of or agreed to by the sponsor. These studies gather additional information about a drug's safety, efficacy, or optimal use

CURRICULUM VITAE

Kelcey G. Patterson, BScH

EDUCATION

- 2009-present Doctor of Philosophy candidate (PhD)
 Department of Microbiology and Immunology, Schulich School of
 Medicine and Dentistry, University of Western Ontario, London, ON
- 2007-2009 Master's of Science candidate (MSc)
 Department of Microbiology and Immunology, Schulich School of
 Medicine and Dentistry, University of Western Ontario, London, ON;
 transferred to Ph.D. program
- 2003-2007 Bachelor of Science Degree with Honours (BScH)
 Department of Biology, Acadia University, Wolfville, NS

RESEARCH EXPERIENCE

- 2013-present **Research Scientist**, Sernova Corp, London, ON
- 2009-present **Ph.D. Candidate**, Department of Microbiology and Immunology,
 University of Western Ontario, London ON
- Thesis: Development of a novel humanized single chain antibody-
 streptococcal superantigen-derived immunotherapy targeting the 5T4
 oncofetal antigen*
- 2007-2009 **M.Sc. Candidate**, Department of Microbiology and Immunology,
 University of Western Ontario, London, ON
- Thesis: Development of Novel Streptococcal Superantigen-Derived
 Tumour-Targeted Immunotherapy*
 Transferred into PhD program to continue research
- 2006-2007 **Laboratory Quality Technician**, Michelin North America Corporation
 Inc., Waterville, NS
- 2005-2007 **B.Sc.H. Honours Thesis Candidate**, Biology Department, Acadia
 University, Wolfville, NS
- Thesis: Determining the potential of isolated bacterial colonies from soil
 contaminated with gasoline and diesel surrounding Alnus rugosa and
 Salix sp. in the role of hydrocarbon degradation in phytoremediation*

RELATED EXPERIENCE

Teaching Experience

- 2012-2013 Undergraduate Mentor
Supervised an undergraduate 4th year thesis project: Arya Afsahi
McCormick Lab, Department of Microbiology and Immunology,
University of Western Ontario, London, ON
- 2011-2013 Undergraduate Tutor
Tutoring 2 undergraduate nursing students in the field of Microbiology
and Immunology, University of Western Ontario, London, ON
- 2010-2012 Teaching Assistant: MicroImm 3600G Laboratory Techniques in
Microbiology and Immunology
Department of Microbiology and Immunology, University of Western
Ontario, London, ON
- 2009-2010 Undergraduate Mentor
Supervised an undergraduate 4th year thesis project: Mathias Scinocca
McCormick Lab, Department of Microbiology and Immunology,
University of Western Ontario, London, ON
- 2007-2010 Teaching Assistant: MicroImm 2100A Biology of Prokaryotes
Department of Microbiology and Immunology, University of Western
Ontario, London, ON
- 2005-2007 Teaching Assistant: Biol2053 Microbial Biodiversity, Biol2073 Animal
Biodiversity, Chem2513 Organic Chemistry 1
Departments of Biology and Chemistry, Acadia University, Wolfville, NS

Leadership Experience

- 2010-2012 Graduate Student Representative for Microbiology and Immunology
Department of Microbiology and Immunology, University of Western
Ontario, London, ON
- 2010-2011 Chair of Infection and Immunity Research Forum Organizing Committee
Department of Microbiology and Immunology, University of Western
Ontario, London, ON
- 2006-2007 Acadia University Biology Society President
Department of Biology, Acadia University, Wolfville, NS
- 2006-2007 Co-Chair of Finances
Canadian Cancer Society Relay for Life, Acadia University, Wolfville, NS

HONOURS AND AWARDS

2009-2012	Western Graduate Research Scholarship, University of Western Ontario (\$2835 per year)
2011	Danone Science Award (Best Student Seminar), University of Western Ontario (\$500)
2011	Top Graduate Poster Presentation, Infection and Immunity Research Forum, University of Western Ontario (\$100)
2011	Microbiology and Immunology Graduate Travel Award, University of Western Ontario (\$1000)
2009	Microbiology and Immunology Graduate Travel Award, University of Western Ontario (\$1000)
2008	Top Graduate Poster Presentation, Canadian Society of Microbiology, Calgary, Alberta (\$100)
2007-2008	Western Graduate Research Scholarship, Microbiology, University of Western Ontario (\$2732)
2007-2008	Schulich Graduate Scholarship, University of Western Ontario (\$784)
2007-2008	Schulich Scholarship for Medical Research, University of Western Ontario (\$804)
2007	Acadia University Student Leadership Award
2004-2007	Clarke K. McLeod Pre-Medical Scholarships, Acadia University (Total: \$6000)
2003-2007	University Scholar, Academic Honours Acadia University
2003-2006	Dr. Lalia B. Chase Scholarship, Acadia University Bursary (Total: \$3900)
2003-2006	The Class of 1923 Scholarship, Acadia University Bursary (Total: \$2100)
2003	Acadia University Entrance Bursary (\$4000)
2003	Nova Scotia Teacher's Union Award (\$250)
2003	Annapolis West Education Centre Alumni Bursary (\$100)

PUBLICATIONS and PRESENTATIONS

Publications

- 2014 K.G.Patterson, J.L.Dixon Pittaro, P.S.Bastedo, D.A.Hess, S.M.M. Haeryfar, J.K.McCormick. 2014. Control of established colon cancer xenografts using a novel humanized single chain antibody-streptococcal superantigen fusion protein targeting the 5T4 oncofetal antigen. PLOS ONE 15; 9(4)
- 2013 R.V.Anantha, K.J.Kasper, K.G.Patterson, J.J.Zeppa, J.Delport, J.K.McCormick. 2013. Fournier's gangrene of the penis caused by *Streptococcus dysgalactiae* subspecies equisimilis: case report and incidence study in a tertiary-care hospital. BMC Infectious Diseases 3:381

Presentations

- 2011 K.G.Patterson, J.L.Dixon, P.S.Bastedo. H.C.Broughton, S.M.M. Haeryfar, D.A.Hess, J.K.McCormick. Development of streptococcal superantigen-derived anti-cancer immunotherapeutics. Poster presentation, Infection and Immunity Research Forum. London, Ontario
Top Graduate Poster Presentation was awarded for this poster.
- 2011 K.G.Patterson, J.L.Dixon, P.S.Bastedo. S.S.Gupta, J.K.McCormick. Development of superantigen-derived anti-cancer immunotherapeutics. Poster presentation, Canadian Cancer Immunotherapy Consortium. Lake Louise, Alberta
- 2011 K.G.Patterson, J.L.Dixon, P.S.Bastedo. S.S.Gupta, J.K.McCormick. Development of superantigen-derived anti-cancer immunotherapeutics. Poster presentation, Canadian Society for Immunology. Lake Louise, Alberta
- 2009 K.G.Patterson, J.L.Dixon, P.S.Bastedo. S.S.Gupta, J.K.McCormick. Development of superantigen-derived anti-cancer immunotherapeutics. Poster presentation, International Society for Biological Therapy of Cancer. National Harbor, Maryland
- 2009 K.G.Patterson, J.L.Dixon, P.S.Bastedo. S.S.Gupta, K.J.Kasper, J.K.McCormick. Development of superantigen-derived anti-cancer immunotherapeutics. Poster presentation, Infection and Immunity Research Forum. London, Ontario
- 2008 K.G.Patterson, J.L.Dixon, P.S.Bastedo. S.S.Gupta, K.J.Kasper, J.K.McCormick. Development of superantigen-derived anti-cancer immunotherapeutics. Poster presentation, Canadian Society of Microbiology Conference. Calgary, Alberta
Top Graduate Poster Presentation was awarded for this poster.
- 2008 K.G.Patterson, J.L.Dixon, P.S.Bastedo. S.S.Gupta, K.J.Kasper, J.K.McCormick. Development of superantigen-derived anti-cancer immunotherapeutics. Poster presentation, Infection and Immunity Research Forum. London, Ontario
- 2005 K. Moore, K. Patterson. E.Reekie, R.Evans, R. Newell, C.Stanley, P.Romkey and C. Bell. The role of bacterial communities of hydrocarbon spill sites in Atlantic Canada. Poster presentation, Canadian Society of Microbiology Conference. Halifax, Nova Scotia

SELECT VOLUNTEER EXPERIENCE

- 2010-2012 Scientific Judge, London District Science & Technology Fair
- 2008-2012 Infection and Immunity Research Forum Organizing Committee Member
- 2007-2010 Microbiology and Immunology Social Committee
- 2005-2007 Member of Volunteer Acadia
- 2004-2007 Wolfville Animal Hospital and Shelter
- 2003-2007 Relay for Life Committee, Canadian Cancer Society
